INDEX.

NAME INDEX.

A Beginner in Relativity, Mathematics at British Universities, 194
Abbot (Dr. C. G.), The Distribution of Energy in Stellar Spectra, 945
Abbott (G.), and W. A. Richardson, The Micropetrography of the Structures of the Magnesian Limestone of Fulwell, 109
Abbott (W. J. Lewis), Chalky Boulder Marl at Hastings, 312
Abercromby of Aboukir and Tullibody (Lord), [death], 583; [obituary article], 617
Ackermann (A. S. E.), Physical Properties of Clay, 124
Adam (N. K.), and J. W. W. Dyer, The Molecular Structure of Thin Films. Part VI., 772
Adams (Prof. E. P.), and Col. R. L. Hippisley, Smithsonian Mathematical Formulæ and Tables of Elliptic Functions, 85
Adams (Dr. W. R. C.), appointed an assistant lecturer and demonstrator to Faraday House Electrical Engineering College, 952
Adamson (A. M.), appointed assistant in the department of Zoology in St. Andrews University, 736
Adamson (Prof. J. W.), conferment upon, of the title of emeritus professor of education by London University, 180
Adamson (R. S.), Preliminary Note on Secondary Growth in some Iridaceæ, 262
Adinolfi (E.), Hall's Effect in Bismuth in the Case of Weak Fields, 595
Aepinus (F. U. T.), bicentenary of the birth of, 868
Ainsworth-Davis (Prof. J. R.), The Resources of the Empire Series. Vol. I. Part I.: Crops and Fruits. Vol. I. Part II.: Meat, Fish, and Dairy Produce, 526
Aitchison (Dr. L.), and W. R. Barclay, Engineering Non-ferrous Metals and Alloys, 427
Aitken (W.), Automatic Telephone Systems. Vol. III., 533
Ajisafe (A. K.), The Laws and Customs of the Yoruba People, 745
van Albada (Col. L. E. W.), Wide-angle Ortho-stereoscopy: its Optical, Practical, and Psychological Advantages, 75
Aldis (J. A.), On the Vibrations of Air in Organ-pipes of Unusual Shapes, 309
Allan (Dr. D. A.), appointed lecturer in Geology in Armstrong College, 915; The Igneous Geology of the Burntisland District, 110
Allbutt (Sir Clifford), The Word "Scientist" or its Substitute, 823
Allee (W. C.), work on Barro Colorado Island, 98
Allis (W. P.), The Damping of the Oscillations of a Hertzian Resonator, 702
Allison (S. K.), G. L. Clark, and W. Duane, Influence on Secondary X-ray Spectra of placing the Tube and Radiator in a Box, 846; and W. Duane, Absorption Measurements of certain Changes in the Average Wave-length of Tertiary X-rays, 112; The Reflection of Characteristic Bromine X-radiation by a Crystal of Potassium Bromide, 559
Allmand (Prof. A. J.), and A. N. Campbell, The Electrodeposition of Manganese, 182
Almagia (R.), Landslips in Italy, 730
Alty (T.), The Cataphoresis of Gas Bubbles in Water, 772
Amadori (M.), Hydrated Active Tartaric Acid, 595
Amar (J.), The Preservation of Living Tissues, 299
Anderson (R. J.), and E. G. Fahlman, A Method for measuring Internal Stress in Brass Tubes, 487
Andrew (G.), Occurrence of Pachytheca in the Buildwas Beds, 810
Andrews (D. H.), and J. Johnston, The Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in Metal Systems, 487
Andrews (E. C.), The Adelaide Meeting of the Australasian Association, 877
Andrews (R. C.), arrival at Urga, Mongolia, 443
Angeli (A.), Constitution of Santonin, 631
Anrep (Dr. G. V.), awarded the William Julius Mickle fellowship of London University, 807
Antoniadi (E. M.), Mars, 586, 702; and others, Mars, 836
Appleton (Dr. E. V.), appointed Wheatstone professor of physics at King's College, London, 208; Geophysical Influences on the Transmission of Wireless Waves, 918; K. G. Emeléus, and M. Barnett, Some Experiments with an α-particle Counter, 182
Arctowski (Dr. H.), The Geothermic Gradient, 872
Armellini (G.), Observations of the Diameter of the Sun, 148
Armstrong (Alice H.), W. Duane, and W. W. Stifler, The Influence on Secondary X-ray Spectra of placing the Tube and Radiator in a Box, 846
Armstrong (A. L.), work at Grime's Graves, 879
Armstrong (Dr. E. F.), presidential address to the Society of Chemical Industry, 133; and J. Allan, Chemistry of Fats, 137
Armstrong (Prof. H. E.), James Dewar, 1842–1923: a Friday evening lecture to the Members of the Royal Institution, on January 18, 1924, 48
d'Arsonval, Bordas, and Touplain, Study of the Waters of the Glaciers of the Mont Blanc Massif, 523
Artom (C.), Variation in the Radio-sensibility of the Cellular Elements in Pecilothermic Organisms, 595
Ashley (Sir William), A Retrospect of Free Trade Doctrine, 229
Ashton (H.), The Gippsland Hairy Cicada, *Tittigarcta crinita*, Dist., 212
Astbury (W. T.), The Rotatory Dispersion of Tartaric Acid, 122; and Kathleen Yardley, Tabulated Data for the Examination of the 230 Space-groups by Homogeneous X-rays, 31
Aston (Dr. F. W.), Photographic Plates for the Detection of Mass Rays, 918; The Mass-spectra of Cadmium, Tellurium, and Bismuth, 717; The Mass Spectra of Zirconium and some other Elements, 273; The Rarity of the Inert Gases on the Earth, 786
Athanasiu (G.), Distribution of Energy in the Mercury Arc Spectrum, 111, 205
Atkins (Dr. W. R. G.), Solubility of Phosphates in Relation to Hydrogen Ion Concentration, 275; Some Poetic Allusions to Phenomena of Plant Biology, 158; The Filtration and other Errors in the Determination of the Hydrogen Ion Concentration of the Soil, 110; and G. T. Harris, Seasonal Changes in the Water and Heleoplankton of Freshwater Ponds, 775
Atkinson (R. d'E.), Vegard's Theory of the Aurora, 881
Atynski (K.), Preparation of Selenides from Selenium Hydride and Metallic Salt Solutions, 263

595399

Auclair (J.), The Probable Cause of the Natural Immunity of Birds towards Human Tuberculosis, etc., 211
Audaut (A.), Opalescence at and near the Critical Point, 255
Audibert (E.), A Necessary Condition for Safe Mining in an Inflammable Atmosphere, 774
Audubert (R.), Photo-voltaic Phenomena, 702
Austen (E. E.), appointed deputy keeper in the department of Entomology of the British Museum (Natural History), 20
Austin (E.), Developments in Power Station Design, 8
Austin (G.), Electricity for Auxiliary Power on Ships, 801
von Auwers (K.), and others, Steric Hindrance and Complex Ring Compounds, 874
Avebury (Lord) [Sir John Lubbock], The Life-work of, 1834–1913. Edited by his daughter, the Hon. Mrs. Adrian Grant Duff, 239
Aydelotte (President), Honours Courses in American Universities and Colleges, 665
Azuma (R.), Thermodynamic Phenomena exhibited in a Shortening or Lengthening Muscle, 73

Babcock (H. D.), Comparison of Wave-lengths with a Fabry and Perot Étalon, 276
Bailey (C. W.), and a Chapter on Theory and Practice, by B. Darwin, The Brain and Golf: Some Hints for Golfers from Modern Mental Science, 271
Bailey (Maj. F. M.), Surveys in Bhutan and Southern Tibet, 656
Bailey (K. C.), Reaction between Ferric Chloride and Potassium Thiocyanate, 775; The Synthesis of Urea from Carbon Dioxide and Ammonia under Atmospheric Pressure, 775; and Mrs. D. F. H. Bailey, The Colorimetric Estimation of Thiocyanates and Cyanates, 146; and J. D. Kidd, Freezing-point of Solutions containing Ferric Chloride and Potassium Thiocyanate, 775
Bailey (Prof. L. H.), Manual of Cultivated Plants: a Flora for the Identification of the most Common or Significant Species of Plants grown in the Continental United States and Canada for Food, Ornament, Utility, and General Interest, both in the Open and under Glass, 748
Baillaud (J.), Absorption in the Atmosphere, 366; Distribution of Energy in Stellar Spectra, 100
Baillie (Prof. J. B.), appointed vice-chancellor of the University of Leeds, 144
Bain (A. D. N.), R. B. Newton and Prof. A. C. Seward, Nigerian Coal Measures, 64
Baird and Tatlock (London), Ltd., Standard Catalogue. Vol. 4, 764
Bairsto (G. E.), The Synchronous and Instantaneous Illumination of Objects Rotating or Vibrating at very High Speeds, 108
Baker (Dr. B. B.), appointed professor of mathematics at the Royal Holloway College, 29
Baker (C.), Catalogue of Microscopes, 514; Catalogue of Second-hand Scientific Apparatus, 655
Baker (E. C. Stuart), The Fauna of British India, including Ceylon and Burma. Birds. Vol. 2. New edition, 427
Baker (H. E.), awarded the Wiltshire prize of Cambridge University, 71
Baker (Prof. H. F.), Principles of Geometry. Vol. 3, 83
Baker (J. L.), The Chemist and the Fermentation Industries, 735
Baker (J. W.), appointed a demonstrator in organic chemistry in Leeds University, 807
Baker (Prof. R. P.), The Rensselaer Polytechnic Institute of Troy, New York, and Science, 808
Baker (R. T.), and H. G. Smith, Wood-fibres of some Australian Timbers: Investigated in reference to their Prospective Value for Paper-pulp Production, 190
Baker (T. Thorne), Photography in Science, Industry, and Medicine, 99
Baker (W.), appointed an assistant lecturer in chemistry in Manchester University, 180
Baldet (F.), and E. M. Antoniadi, Observations of Cloud-capped Protuberances which recently appeared on Mars, 810
Balfour (Dr. A.), The Teaching of Public Health, 480
Balls (Dr. W. L.), Cotton in Australia, 819; Frequency Curves of Genera and Species, 10; and others, Research on Textile Fibres, 27
Banerji (S. K.), Microseisms associated with the Incidence of the South-west Monsoon, 576
Barbour (Dr. A. H. Freeland), gift to Edinburgh University, 952
Barclay-Smith (Lieut. E. A.), Wave-power Transmission, 392
Barcroft (Prof. J.), Sir William Bayliss, 474; Mountain Sickness, 90; A. E. Mirsky, and S. Oinuma, Correlation between the Spectra of various Hæmoglobins and their Relative Affinities for Oxygen and Carbon Monoxide, 809
Barff (H. E.), resignation of the posts of warden and registrar of Sydney University, 71
Barger (Prof. G.), The Remuneration of the Staff of Edinburgh University, 652; and F. J. Eaton, Blue Adsorption Compounds of Iodine, 948
Barker (Principal E.), The Nature and Conditions of Academic Freedom in Universities, 232
Barker (J. Ellis), Cancer: How it is caused, How it can be prevented, 496; and The Reviewer, The Causation of Cancer, 644; On Review of Cancer: How it is caused, How it can be prevented, 691
Barkla (Prof. C. G.), Some Recent Researches on X-rays: the J-phenomenon, 753
Barnard (K. H.), The Digestive Canal of Isopod Crustaceans, 336
Barnes (C. L.), The Ben Nevis Observatory, 810
Barnes (Rev. Canon E. W.), appointed Bishop of Birmingham, 200
Barns (Capt. T. A.), Across the Great Craterland to the Congo: a Sequel to "The Wonderland of the Eastern Congo," 785
Barratt (S.), Absorption Spectra of Mixed Metallic Vapours, 827
Barret (H. P.), and Nannie M. Smith, Culture of an Endamœba from the Turtle, 172
Barton (H. A.), Negative and Doubly Charged Positive Ions in Argon, 826
Barton (V. P.), and F. L. Hunt, Molecular Dimensions of Celluloid, 861
Barus (Dr. C.), Density and Diffusion Measurement by Displacement Interferometry in Extreme Cases, 703
Bastings (L.), The Decay Constant of Radium Emanation, 918
Bates (L. F.), The Range of α-particles in Rare Gases, 773
Batuecas (T.), Revision of the Compressibility of Methyl Oxide and the Molecular Weight of this Gas, 631; Revision of the Weight of the Normal Litre of Methyl Oxide, 452
Baur (Prof. E.), Breeding Experiments with Antirrhinum, 730
Baxter (E. F.), appointed an assistant lecturer in mathematics in Sheffield University, 107
Baylis (H. A.), Cestodes from Whales of the Genus Balænoptera, 917
Bayliss (Sir William), [death], 364; [obituary article], 474
Bean (W. J.), Rhododendrons, 636
Beard (Dr. J.), [obituary article], 904
Bearsted (Lord), gift to Sheffield University, 209
Beck (C.), The Microscope. Part 2. An Advanced Handbook: a Sequel to "The Microscope, a Simple Handbook," 571
Beck, Ltd. (R. and J.), A Portable Microscope, 517
Becker (Dr. A.), The Emission of Electrons caused by α-rays, 588
Becker (J. A.), The Compton and Duane Effects, 703
Becker (M. L.), Medieval Metallurgy, 837
Bebbe (W.), Galapagos: World's End, 411
de Beer (G. R.), Growth, 709; The Histology of the Pituitary Body, 917
Beers (C. D.), Amœba Feeding on Frontonia, 171
Beetlestone (N. C.), Water-content of Yeast Cells, 872
Beilby (Sir George), [death], 199; [obituary article], 361
Bell (Gertrude Lowthian), Amurath to Amurath. New edition, 606
Bellingham and Stanley, Ltd., A New Spectrometer, 839

Bengough (G. D.), and R. May, Seventh Report to the Corrosion Research Committee of the Institute of Metals, 487
Benham (C. E.), The Scotoscope, 11
Bennett (F. T.), Outlines of Fungi and Plant Diseases: for Students and Practitioners of Agriculture and Horticulture, 306
Bennie (W. G.), The Education of the Native, 802
Bentham (G.), revised by Sir J. D. Hooker. Seventh edition, revised by Dr. A. B. Rendle, Handbook of the British Flora: a Description of the Flowering Plants and Ferns Indigenous to, or Naturalised in, the British Isles; for the use of Beginners and Amateurs, 379
Benton (W. E.), Organ-pipes of Unusual Shapes, 573, 787
Bernal (J. D.), The Structure of Graphite, 738
Bernauer (Dr. F.), Die Kolloidchemie als Hilfswissenschaft der Mineralogie und Lagerstättenlehre und ihre Anwendung auf die metasomatischen Blei-Zink-Lagerstätten, 568
Berry (A. J.), Thallous Thallic Halides, 731
Berthoud (Prof. A.), translated by Eden and Cedar Paul, The New Theories of Matter and the Atom, 928
Bertin (L. E.), [death], 724
Bertrand (G.), The Stifling of Silkworm Cocoons, 481; and H. Nakamura, The Comparative Physiological Importance of Iron and Zinc, 299
de Beuzeville (W. A. W.), and M. B. Welch, A New Species of Eucalyptus from Southern New South Wales, 919
Bhatnagar (Prof. S. S.), The Indian Institute of Science, Bangalore, 538
Bhattacharyya (Bisvesvar), The Age of the Padmā, 372
Bhattasali (N. H.), origin of "Imitation Gupta Coins," 587
Bickerton (Prof. A. W.), elected an honorary member of the New Zealand Astronomical Society, 834
Bidder (Dr. G. P.), Emission of Volcanic Gases, 50
Bigourdan (G.), Occultation of Mars by the Moon, 845; The Determination of Time, and the Modified Use of the Method of Corresponding Heights, 147
Bilham (E. G.), Fog at the Scilly Isles, 838
Billon (P.), The Primary β-amino-alcohols corresponding with the General Formula $R . (N . H_2) . CH . CR_1R_2 (CH_2 . OH)$, 955
Binnie (A. M.), awarded the John Winbolt prize of engineering of Cambridge University, 700
Bird (G.), recommended the award of a Robert Blair Fellowship, 180
Bird (W. H.), Collective Index of the Journal of the Institute of Brewing, 1911 to 1923, 677
Birge (Prof. R. T.), Active Nitrogen, 642
Bjerknes (Prof. V. K. F.), The Forces which lift Aeroplanes, 472, 508
Bjerrum (N.), The Dissociation Constant of Methyl Alcohol, worked out together with Miss Unmack and L. Zechmeister, 147
Black (D. H.), Some Electrical Properties of Liquid Sulphur, 76; The β-ray Spectrum of Mesothorium 2, 773
Black (N. H.), Laboratory Experiments in Chemistry: to accompany Black and Conant's "Practical Chemistry," 346; Laboratory Experiments in Practical Physics: to accompany the revised edition of Black and Davis' "Practical Physics," 929
Blackman (Dr. A. M.), The Rock Tombs of Meir. Part 4, 461
Blackman (Dr. F. F.), and others, The Physiology of Crop Yield, 293
Blackman (Prof. V. H.), Physiological Aspects of Parasitism, 231
Blagg (Miss M. A.), β Lyræ, 254
Blow (T. B.), Charophyta collected during a Recent Visit to Madagascar, 110
Blum (W.), and G. B. Hogaboom, Principles of Electroplating and Electroforming (Electrotyping), 272
Bogert (M. T.), and M. Chertcoff, A New Group of Dyes from Poison Gases through the 2-Aminothiazoles as Intermediates, 920; and P. S. Nisson, The Synthesis of Terephthal Green and Terephthal Brilliant Green from Cymene, 920; and J. J. Ritter, The Constitution of the so-called "Pechmann Dyes," etc., 703
Bogitch (B.), The Oxidation of Chromite and the Preparation of Chromates, 210
Bohr (H.), Quasi-periodic Functions, 148
Bolton (Dr. H.), Museums and the British Empire, 149
Bolton (L.), Time Measurement: an Introduction to Means and Ways of reckoning Physical and Civil Time, 531
Bonacina (L. C. W.), Barogram Analysis in Weather Forecasting, 393; The Maximum Recorded Temperature of the Air and its Circumstances, 294
Bond (C. J.), The Leucocyte in Health and Disease: being an Enquiry into certain Phases of Leucocytic Activity, 784
Bond (W. N.), The Flow of Compressible Fluids, treated dimensionally, 108; The "Hole, Slot and Plane" Geometrical Constraint, 502
Bordet (J.), The Current Theories of Anaphylaxy, 335
Borel (Prof. É.), Éléments de la théorie des probabilités. 3e édition, 303
Borradaile (Dr. L. A.), The Animal and its Environment: a Text-book of the Natural History of Animals, 152
Borthwick (Dr. A. W.), and others, Relation of Forest Pathology to Silviculture, 293
Botha (G.), The Public Archives: their Value to Scientific Research, 802
Bothe (Dr. W.), Estimation of Radioactive Substance by γ-rays, 65
Bouny (F.), Leçons de mécanique rationnelle, professées à l'École des Mines et de Métallurgie Faculté technique du Hainaut à Mons. Tome Ier, 674
Bourguel (M.), A General Method for the Preparation of True Acetylenic Hydrocarbons, 702; The Transformation of the Substituted Acetylene Hydrocarbons into True Hydrocarbons by Sodium Amide, 32
Bourion (Prof. F.), Thermochimie, 240
Bouvier (Prof. E.-L.), Faune de France, 7; Pycnogonides, 272
Bovis (P.), The Absorption Spectrum of Bromine, 31
Bowen (I. S.), and Dr. R. A. Millikan, The Series Spectra of the Stripped Boron Atom (B III.), 112
Bower (Prof. F. O.), The Work of, 511
Bowie (W.), Gravity Observations on the Indian Ocean and the Results of their Isostatic Reduction, 930; Nature of Isostatic Compensation, 730
Bowman (Dr. A.), appointed lecturer on the scientific study of fisheries in Aberdeen University, 915
Boycott (Prof. A. E.), Life History of the Pearl Mussel, 276
Boyle (Mary E.), Man before History: a Short Account of Prehistoric Times, 410
Boys (Prof. C. V.), awarded the Rumford medal of the Royal Society, 724; presented with the Rumford medal, 841; awarded the Duddell Memorial medal of the Physical Society of London, 944
Braak (Dr. C.), Humidity in the Netherland Indies, 947; Temperature in the Netherland Indies, 101
Bradley (F. H.), [death], 476; [obituary article], 546
Bragg (Sir William H.), Analysis of Crystal Structure by X-rays, 248; opening of the new College of Pure Science at Durham University; an honorary degree conferred upon, by Durham University, 557; The Carbon Atom in Crystalline Structure, 862
Bragg (Prof. W. L.), Influence of Atomic Arrangement on Refractive Index, 73; and Prof. S. Chapman, A Theoretical Calculation of the Rhombohedral Angle of Crystals of the Calcite Type, 737; and others, Crystal Structure, 912
Brambell (F. W. R.), Sex Determination, 804
Brammall (A.), Lime as a Constituent of certain Important Rock-forming Minerals, 774
Branford (V.), Living Religions: a Plea for the Larger Modernism, 562
Brauner (Prof. B.), Prof. Ian Deyl, 57; Prof. I. Hlava, 942; Prof. A. Mrázek, 322; Prof. F. Počta, 17
Breasted (Prof. J. H.), Historical Tradition and Oriental Research, 559, 754
Brehm (V.), Diagnoses of new Entomostraca. Part III., 263
Breit (G.), The Quantum Theory of Dispersion, 310
Brennen (J. H.), The Carrying down of Polonium by Colloids, 299

Bridel (M.), The Fermentation Hydrolysis of Gentiacauline, 739; The Hydrolysis of Monotropitine by a Ferment, 845
Bridgman (P. W.), Some Properties of Single Metal Crystals, 920
Briggs (Rev. F. S.), A Sidelight on Bird Migration, 574
Briggs (Prof. H.), Apparatus to facilitate the Use of an Oxygen-carbon Dioxide Mixture on the Treatment of Carbon Monoxide Poisoning, 110
Brimley (R. C.), Absorption of Vapours of Various Liquids by Cotton, 432
Brioux (C.), Saturation in the Soil of Sulphuric Acid utilised for the Destruction of Weeds, 211; The Influence of Urea, used as Manure, on the Reaction of the Soil, 811
British Dyestuffs Corporation, Ltd., List of Fine Organic Chemicals for Research Work, etc., 203; Medicinal Products, 836
Briton-Jones (H. R.), Variability in Fungi, 482
Britten (J.), [obituary article], 583
Britton (H. T. S.), The Composition of Chromic Acid, 589
Britton (N. L.), and J. N. Rose, The Cactaceæ: Descriptions and Illustrations of Plants of the Cactus Family. Vol. 4, 424
Brockwell (Rev. C. A. Brodie), The Transition from Ancient to Modern Arithmetic, I., II.: Calculation by Deficients, 296
Brodetsky (Prof. S.), Aeronautical Science, 566; appointed professor of applied mathematics in Leeds University, 208; Mathematics for Engineers, 674; Mathematics of Relativity, 339; The Teaching of Mathematics in France, 45
Brodrick (Miss Mary), gift to University College, London, for a prize in geography, 807
de Broglie (L.), De Broglie's Theory of the Quantum and the Doppler Principle, 51
Brooks (C. E. P.), Lake Victoria and the Flow of the Yala River, 536; The Problem of the Mild Polar Climates, 953; The Rainfall in the British Isles, April to August, 479
Brooks (F. T.), Imperial Botanical Conference, 293; and others, Relation of Plant Pathology to Genetics, 293
Brough (P.), Studies in the Epacridaceæ. I., 212
Broughall (L. St. Clair), awarded the Dunning scholarship of Cambridge University, 208
Brown (Prof. E. W.), An Explanation of the Gaps in the Distribution of the Asteroids according to their Periods of Vibration, 264
Brown (N. E.), The Cactus Family, 424
Browne (F. Balfour), appointed University lecturer in zoology in Cambridge University, 842
Browne (W. R.), The Physiography and Geology of the Upper Hunter River, 559; and W. S. Dun, The Stratigraphy of the Basal Portion of the Permo-Carboniferous System in the Hunter River Valley, 919
Brownlie (D.), Pulverised Fuel, 65
Bruce (Maj.-Gen. Sir David), Prevention of Disease, 213
Bruce (J.), with an appendix by R. H. Parsons, Power Station Efficiency Control, 571
Bruggencate (Dr. P. ten), Spiral Structure in Star Clusters, 100
de Bruin (T. L.), and Prof. P. Zeeman, On the Spectrum of Ionised Potassium in Connexion with the Red and Blue Spectrum of Argon, 352
Brun (A.), A New Variable Star, with a Period probably very short, 810
Brunner (Sir John), Address to the Association of British Chemical Manufacturers, 200
Brunt (Capt. D.), The Origin of Tropical Revolving Storms, 389
Brus (G.), The Oxidation of Nopinene by Permanganate, 559
Bruttini (Prof. A.), Uses of Waste Materials: the Collection of Waste Materials and their Uses for Human and Animal Food, in Fertilisers and in certain Industries, 1914–1922, 460
de Bruyne (N.), The Electrolytic Rectifier: for Electrical Engineers, Physicists, and Wireless Amateurs, 462
Bryce (Prof. T. H.), Early Development of the Human Embryo, 729
Brylinski (E.), The Carrying away of the Ether and the Aberration of Stars, 955; The Possibility of Thermal Disturbance in Michelson's Experiment, 767
Bryson (T.), Theory and Practice of Mine Ventilation: a Text-book for Students and a Book of Reference for Managers and Under-managers, 7
Buchanan-Wollaston (H. J.), Growth-rings of Herring Scales, 348
Buck and Perkin, Pseudo-Epiberberine, 589
Buckley (F.), The Glass-houses of the Leeds District in the Seventeenth, Eighteenth, and Early Nineteenth Centuries, 955
Budgen (Dr.), Fusible Alloys, 173
de Buén (Prof. O.), elected president of the Section of Oceanography of the International Union of Geodesy and Geophysics, 697
Buermeyer (L.), and others, An Introduction to Reflective Thinking, 785
Buller (Prof. A. H. R.), Experiments on Sex in Mushrooms and Toadstools, 826
Burchell (J. P. T.), Some Stratified Finds on the North Kent Coast, 878
Burdett (Nelly), The Problem of the Mentally Defective, 288
Bureau (R.), and A. Viant, Meteorological Conditions and the Appearance of Certain Atmospheric Disturbances in Receiving Apparatus of Wireless Telegraphy, 396
Burford (H. G.), awarded the Institution medal of the Institution of Automobile Engineers, 762
Burke (Miss Katharine A.), [death], 166; [obituary article], 250
Burkill (I. H.), Botany of the Abor Expedition, 516
Burn (D. L.), elected Wrenbury scholar in economics in Cambridge University, 180
Burnett (Major J. C.), Hyper and Ornate Magic Squares, 15th and 16th Orders, 821
Burt (Dr. C. L.), appointed professor of education at the London Day Training College, 29; Prof. Whipple, and Prof. Buckingham, Tests for Scholarships and Promotion, 556
Burton (Dr. E. F.), Surface Tension and Fine Particles, 502
Burton (W.), Chinese Pottery, 342
Busacca (A.), Structure of the Living Crystalline Fibre, 262
Butler (Dr. H.), The Microscopy of the Living Eye, 179
Büttikofer (Dr. J.), elected a foreign member of the Zoological Society of London, 944
Buxton (P. A.), Animal Life in Deserts, 22

Cabannes (J.), and A. Lepape, The Diffusion of Light by Krypton and Xenon, 371
Cady (F. E.), Abney Sectors in Photometry, 683
Cajori (Prof. F.), Sir Isaac Newton and his Work, 60
Callizo (M.), A World Record for Altitude, 586
Calman (Dr. W. T.), Chimæras Dire, 11, 467
Calmette (Prof.), New Anti-tuberculosis Vaccine, 18; presented with the Weber-Parkes prize and medal, 654
Calvert (W. J. R.), Physics. Vol. I.: Mechanics, Heat and Heat Engines, 344
Cambage (R. H.), Australian Resources of Liquid Fuels, 299; Landslides near Picton and Notes on the Local Vegetation, 956
Campbell (Dr. J. E.), [death], 547; [obituary article], 651
Campbell (J. W.), The Drift of Spinning Projectiles, 31
Campbell (Dr. N. R.), Théorie quantique des spectres. La Relativité. Traduit de l'anglais par A. Corvisy, 565; The Word "Scientist" or its Substitute, 788; B. P. Dudding and J. W. Ryde, A Substitute for the McLeod Gauge, 276, 467
Cannon (W. B.), and A. Querido, The Rôle of Adrenal Secretion in the Chemical Control of Body Temperature, 264; and J. R. Pereira, Increase of Adrenal Secretion in Fever, 264
Cantab, Agricultural Research, 465
Cappelletti (C.), The Vegetation of Resins, 631

Woolcock (W. J. U.), The Benefits accruing from close Co-operation of the Scientific and Industrial Branches of Chemistry, 584
Woolnough (W. G.), and J. L. Somerville, The Geology of the Irwin River Valley of Western Australia, 300
Worcester (D. C.), [death], 96
Wright (C. S.), Aurora, Potential Gradients, and Magnetic Disturbance, 466
Wright (G.), appointed a lecturer in surgical pathology in Manchester University, 180
Wright (J. N.), appointed lecturer in logic and psychology in University College, Dundee, and the United College, St. Andrews, 593
Wright (W. H.), Prof. E. C. Slipher, Prof. R. Trumpler, Martian Photography, 798
Wrigley (P. R.), appointed a lecturer in surgical pathology in Manchester University, 180
Wyld (W.), The Manufacture of Sulphuric Acid (Chamber-process) ("The Manufacture of Acids and Alkalis," by G. Lunge. Completely revised and rewritten under the editorship of Dr. A. C. Cumming, Vol. 2), 818
Wynne (Prof. W. P.), The Work of Russian Chemists up to 1914, 662

Yamamoto (R.), Physical Constitution of the Earth, 172
Yeates (Dr. T.), appointed to the S. A. Courtauld chair of anatomy at the Middlesex Hospital Medical School, 665
Yonge (C. M.), Feeding and Digestion in Nephrops, 63
Yorke (Prof. W.), The Malaria Treatment of General Paralysis, 615
Young (F. D.), and C. C. Cate, Damaging Temperatures and Orchard Heating in the Rogue River Valley, Oregon, 370
Younghusband (Sir Francis), Wonders of the Himalaya, 673
Yule (G. U.), Frequency Curves of Genera and Species, 10; The Growth of Population and the Factors which control it, 917

Zachmann (Dr. E.), Conductivity of Metallic Vapours, 368
Zammit (Dr.), and Dr. Singer, Prehistoric Representations of the Human Form from Malta and Gozo, 391
Zeiss (Carl), A New Form of Orrery, 203; A New Loop Galvanometer, 662
Zinsser (Prof. H), Infection and Resistance: an Exposition of the Biological Phenomena underlying the Occurrence of Infection and the Recovery of the Animal Body from Infectious Disease; with a Consideration of the Principles underlying Specific Diagnosis and Therapeutic Measures. New edition, 677
Zsigmondy (Prof. R.), elected a corresponding member of the Vienna Academy of Sciences, 253

TITLE INDEX.

A, Factor, Attempts at the Identification of the, M. Javillier, P. Bauer, and Mlle. S. Levy-Lajeunesse, 845
Abderhalden's Handbuch der biologischen Arbeitsmethoden. Lief. 118, Abt. 2, Heft 4, 100
Aberdeen University: conferment of degrees on Dr. M. C. Grabham and H. E. Magee, 106; appointments in, 557; Dr. A. Bowman appointed lecturer on the Scientific Study of Fisheries; Prof. A. Findlay at Leland Stanford University as substitute professor of chemistry, 915
Aberrational Equations, A General Solution of the First Order, T. Smith, 75
Abney Sectors in Photometry: G. F. Wood, 466; F. E. Cady, 683
Abnormal Conditions, Inheritance of, Dr. C. Wriedt, 206
Abor Expedition, Botany of the, I. H. Burkill, 516
Abram's Cult in Medicine, The, 525
Absorption in the Atmosphere, J. Baillaud, 366
Academic Freedom in Universities, The Nature and Conditions of, Principal E. Barker, 232
Acetic Acid, Action of, on Hydrated Metallic Salts, A. Recoura, 210
Acetoacetic Esters, Condensation of, with Malonic Esters, H. Gault and H. Klees, 667
Acetylene Hydrocarbons, The Transformation of the substituted, into True Hydrocarbons by Sodium Amide, M. Bourguel, 32
Achromatism in Telescopes, The Choice of Wave-lengths for, Prof. T. Townsend Smith, 536
Acidophilus Milk, Prof. L. F. Rettger, 101
Acids, Bases, and Salts, Prof. E. C. Franklin, 767
Acoustic Method of Depth Sounding for Navigation Purposes, Early Canadian Experiments on the, Prof. L. V. King, 122
Acoustical Problems, Major W. S. Tucker, 688
Acoustics: of Buildings: including Acoustics of Auditoriums and Sound-proofing of Rooms, Prof. F. A. Watson, 85; of Halls, Prof. F. R. Watson, 327
Acta phyto-chimica, 389
Activated Sludge, The Study of, L. Cavel, 956
Activity-measurement by the Partition Method, I., B. Cavanagh, 74
Adaptation, The Mechanism of, Prof. L. Diels, 624
Adelaide University, Report for 1923, 209
Admiralty Gun-metal, Influence of Casting Temperature and Mass on the Physical Properties of, F. W. Rowe, 522
Adrenal Secretion, The Rôle of, in the Chemical Control of Body Temperature, W. B. Cannon and A. Querido, 264
Adsorption: J. H. Mathers and A. J. Stamm, 24; and Cataphoresis, K. v. d. Grinten, 256; Anomalous, J. B. Speakman, 352
Adult Education: Classes in Buffalo, 701; in Ireland, G. Fletcher, 261
Aeronautical: Research: 519; Committee, Government, Report of the, 1923–24, 519; Science: Prof. S. Brodetsky, 566; Elementary, I. B. Hart and W. Laidler, 566
Aeroplane, Circumnavigation of the Earth by, 439
Aeroplanes: and Engines, New, 585; The Forces which lift, Prof. V. K. F. Bjerknes, 472, 508; Major A. R. Low, 719
Africa: Central, Laws and Customs in, L. C. G. Clarke, 745; *East*: No. 1, 585; White and Black in, a Record of Travel and Observation in Two African Crown Colonies, H. Norden, 745; The Freshwater Algæ of, V., F. E. Fritsch and Florence Rich, 212; Tropical, Nature and Man in, 420
After-images, The Law of Recurrence and Decay of, Winifred J. Smith, 110
Agricultural: Departments of the Non-self-governing Dependencies, the Recruitment and Training of Officers for the, Appointment of a Committee on, 479; Education and Research, Further Government Grant for, 476; Research: Cantab, 465; Sir E. J. Russell, 641; Rites and the Kingship, Sir William Ridgeway, 765
Agriculture and Fisheries, Ministry of, the fishery publications of the, 202
Agrikulturchemie, Prof. F. Honcamp and Dr. O. Nolte, 748
Air: Archæology from the, O. G. S. Crawford, 580; Congress, International, Report of the, 61; Effect of the Source of, on its Temperature at 4000 feet and 10,000 feet, Miss L. F. Lewis, 109; in Trains, Trams, and Buses, The Cooling Power of the, Leonard Hill, with the co-operation of M. Brad, 246; Survey and Archæology, O. G. S. Crawford, 570; Survey Committee, Report of the, No. 1, 1923, 195; Upper, Investigations, 169; Vibrations, Slow, from Large Explosions, P. Villard, 766
Airships, Progress and Performances of, 548
Albatross, The Flight of the, P. Idrac, 211
Albino Mice, Congenital Eye Anomalies in, E. S. Pearson, 433
Alchemy, Old and New, Dr. P. D. Foote, 549
Alcohol: Dilute, Action of, on Human Subjects, W. R. Miles, 559; Influence of, on Duration of Life, Prof. R. Pearl, 264
Algebra, The Psychology of, Prof. E. L. Thorndike and others, 423
Algebraic and Transcendental Equations, A Series Formula for the Roots of, A. C. Aitken, 919
Algebras and their Arithmetics, Prof. L. E. Dickson, 532
Algerian Hills, Native Life in the, Capt. M. W. Hilton-Simpson, 807
Algologique, Revue, 61
Algol Variables, Studies of, R. S. Dugan, 444
Alkali: Cyanides in Aqueous Solution, The Hydrolysis of, B. Harman and F. P. Worley, 882; Metals, Vapours of, Thermionic Effects caused by, I. Langmuir and K. H. Kingdon, 882
Alkyloxyacids, The Electrolysis of Salts of, D. A. Fairweather, 954
Alloys: Fused, Electrolytic Conduction in, Part III., R. Kreman, R. Kienzl, and R. Markl; Part IV., R. Kreman, R. Müller, and H. Kienzl; Part V., R. Kreman, R. Müller, and R. Ortner, 183; Fusible, Dr. Budgen, 173
Altitude: The Physiology and Pathology of, Foundation of a Prize for the, 289; Record, World, M. Callizo, 586
Aluminium: and Magnesium, Series in the Spectra of, in the Extreme Ultra-Violet, Prof. T. Lyman, 641; Atomic Weight of, H. Krepelka, 589; Commercial, Influence of the Velocity of Cooling on the Properties of, L. Guillet, 111; Sulphide, Action of, on Certain Organic Compounds, G. R. Levi and G. Natta, 148
American: Association, the next meeting of the, 444; Astronomical Society, Prof. A. S. Eddington elected an honorary member of the, 366; Cambrian Geology and Palæontology, Dr. C. D. Walcott, 482; Council on Education, Activity of the, 843; Decorative Art, Primitive, Interpretations of, G. C. Robson, 381; Oil Chemists' Society, establishment of a journal of the, 202; Universities and Colleges, Honours Courses at, President Aydelotte, 665
Amerind Type from China, An, Prof. Seligman, 255
Ammonia: Exploding, with Electrolytic Gas, Prof. J. R. Partington and A. J. Prince, 839; The Production of, from Amino Nitrogen by the Microsiphonideæ of the Soil, G. Guittonneau, 559
Ammonifying Power of Arable Soil, R. Perotti and F. Aureli, 262
Ammonium Dimolybdomalate, Some Properties of, E. Darmois and A. Honnelaitre, 667
Amœba Feeding on Frontonia, C. D. Beers, 171
Amorites, The, Prof. A. H. Sayce, 765
Amurath to Amurath, Gertrude Lowthian Bell. New edition, 606
Anaerobiosis in Arable Soil, The Study of, S. Winogradsky, 810
Analytical Methods for Certain Metals, etc., R. B. Moore and others, 135
Anaphylaxy, The Current Theories of, J. Bordet, 335

Anatolica, H. C. Luke, 428
Ancient: Flint Implements at Cromer, Further Discoveries of, J. Reid Moir, 242; Hunters and their Modern Representatives, Prof. W. J. Sollas. New edition, 408
Anglo-Dutch Telephone Cable between Domburg and Aldeburgh, Laying of an, 478
Animal: Life in Deserts, P. A. Buxton, 22; Parasitology, Prof. H. B. Ward, 392; Studies, Prof. J. A. Todd, 412; The, and its Environment: a Text-Book of the Natural History of Animals, Dr. L. A. Borradaile, 152; Wax, The Decomposition of, A. Mailhe, 299
Animals, The Sense-Organs of, Prof. J. Graham Kerr, 602
Annuitants, The Mortality of, 1900–1920: Investigation and Tables, W. Palin Elderton and H. J. P. Oakley, 855
Annular Plate, The Elastic Stability of an, W. R. Dean, 74
Antarctic: Meteorology, 853; Sea-ice, Problems of, R. W. James, 800
Anthrax: Symptomatic, and Gas Gangrene in Cattle, E. Leclainche and H. Vallée, 111; The So-called "Intestinal," G. Sanarelli, 811
Anthropology, The Cinematograph in, 807
Antimony, The Atomic Weight of, P. F. Weatherill, 911
Antiquity of Man in California, Dr. J. C. Merriam, 204
Anti-Relativity Theory, An, Prof. La Rosa, 290
Antirrhinum, Breeding Experiments with, Prof. E. Baur, 730
Anti-tuberculosis Vaccine, New, Prof. Calmette, 18
Ants, Dolichoderine, The Thermokinetics of, H. Shapley, 920
α-Particle Counter, Experiments with an, Dr. E. V. Appleton, K. G. Emeleus and M. Barnett, 182
α-Particles in Rare Gases, The Range of, L. F. Bates, 773
Apes and Man, The Morphology and Evolution of the, Dr. C. F. Sonntag, 639
Aphids, The Symbiotic Organ in, L. B. Uichanco, 204
Apple Leaves and the Epidermis of Apples, The Immediate Principles contained in, G. Rivière and G. Pichard, 739
Apples in Storage, Fungi rotting, M. N. Kidd and A. Beaumont, 872
Aquarium Technique, Dr. Monica Taylor, 752
Aqueous Vapour Pressure of Capillary Systems, The Indirect Measurement of the, by the Freezing-point Depression of Benzene, E. M. Crowther and A. N. Puri, 74
η Aquilæ, Atmospheric Pulsation of the Cepheid Variable, W. C. Rufus, 264
Arabic Numerals, Dr. K. Mischke, 946
Arabische Alchemisten. I: Châlid ibn Jazîd ibn Mu'âwija, Prof. J. Ruska, 427
Arcella polypora, Interactions of Protoplasmic Masses in, B. D. Reynolds, 326
Arcenthobium Oxycedri, etc., Development of the Anthers and the Meiotic Division of the Pollen Mother Cells in, A. Pisek, 183
Archæology from the Air, O. G. S. Crawford, 580
Architects, The International Congress of, 200
Arc Relays, Some Electro-optical Applications of, L. Dunoyer and P. Thoulon, 523
Arctic: Dr. Stefansson's Geographical Discoveries in the, 19; Expedition, Capt. K. Rasmussen on his, 869; proposed new expedition to the, L. Koch, 797
Argentina, The Oilfields of, C. Hunter, 800
Argentine, Tertiary and Cretaceous Fossils from the, M. Doello-Jurado, 910
Argon: Effect of, on Certain Spectra, R. C. Johnson and W. H. B. Cameron, 74; Negative and Doubly Charged Positive Ions in, H. A. Barton, 826; Solidified, The Crystalline Structure of, F. Simon and Fräulein C. von Simson, 292
Aristida, North American Species of, A. S. Hitchcock, 482
Arithmetic: Ancient and Modern, 296; The Transition from Ancient to Modern, I., II., Rev. C. A. B. Brockwell, 296
Arithmetica Logarithmica, H. Briggs, Tercentenary of the, 693
Arley Seam of the Lancashire Coalfield, The, 692
Armourers and Brasiers Company's Research Fellowship, Miss C. F. Elam appointed to the, 62
Armstrong College, Dr. D. A. Allan appointed lecturer in Geology in, 915
Art, The Nature of, an Open Letter to the Professor of Poetry in the University of Oxford, Prof. J. A. Smith, 569
Art-forms in Nature, Sir Theodore A. Cook, 52
"As if," The Philosophy of, a System of the Theoretical, Practical and Religious Fictions of Mankind, Prof. H. Vaihinger. Translated by C. K. Ogden, 714
Asia: Central, Exploration in, 338; "Innermost": its Geography as a Factor in History, Sir Aurel Stein, 805
Asiatic Expeditions of the American Museum of Natural History, Dr. H. F. Osborn, 504
Aśmakas, The, or Assakas in Ancient India, B. C. Law, 372
Assurances sur la vie: calcul des primes, H. Galbrun. (Traité du calcul des probabilités et de ses applications, É. Borel. Tome 3: Les Applications de la théorie des probabilités aux sciences économiques et biologiques, fasc. 1), 303
Assyrian Medical Texts, from the originals in the British Museum, R. Campbell Thompson, 48
Asteroids, The Gaps in the Distribution of the, according to their Periods of Vibration, Prof. E. W. Brown, 264
Astronomical: Day, The, 622; Measurements, Precise, A Statistical Discussion of Sets of: II., E. B. Wilson and W. J. Luyten, 263; IV., E. B. Wilson and W. J. Luyten, 920; Society of the Pacific, the Bruce Medal of the, awarded to Prof. A. S. Eddington, 762

ASTRONOMICAL NOTES.

Comets:
Encke's Comet, L. Matkiewicz, 62; Encke's Comet, 203, 366, 444; New Comet, 1924 *c*, 480; Finsler's Comet, 1924 *c*, 514; Orbits of Comets, 514; Comets, 586; Finsler's and Encke's Comets, 655; Skjellerup's and Grigg's Comets, Crawford and Meyer, 871
Instruments:
Eyepieces used by Sir William Herschel, 21; A New Form of Orrery, 203; Solar Spectrograph for the Poulkovo Observatory, 325; The Thermopile used for measuring Star Magnitudes, 390; Telescopes in the Southern Hemisphere, 655; The Johannesburg Refractor, Dr. Innes, 908
Meteors:
The Perseids of 1924, W. F. Denning, 290; The November Meteors, W. F. Denning, 603; Fireballs, W. F. Denning; E. G. Fenton, 764; The Great Fireball of November 11, W. F. Denning, 836
Observatories:
Report of the Cape Observatory, Dr. H. Spencer Jones, 21; Report of the Bergedorf Observatory, 62; Annuaire de l'Observatoire Royal de Belgique, 1925, 325; Annual Report of the Solar Physics Observatory, Cambridge, 480; The Dominion Astrophysical Observatory, Victoria, B.C., 764
Planets:
Minor Planets, C. J. Merfield; Dr. Witt, 21; Total Lunar Eclipses, W. J. Fisher, 62; Uranus, W. F. Denning, 170; The Total Lunar Eclipse of August 14, 203; The Opposition of Mars, 254; Mercury a Morning Star, 444; Mars, M. Antoniadi, 586; Planet or Comet?, 655; Minor Planets, 693; The Baade Planet, 728; Martian Photography, W. H. Wright; Prof. E. C. Slipher; Prof. P. Trumpler, 798; Observations of Mars, 836; Combined Observations of the Moon, 908; The Baade Planet, Dr. Stracke, 908; Brightness of Planets and Stars, C. Schoch, 945
Stars:
The Lesser Magellanic Cloud, Prof. H. Shapley, 100; Distribution of Energy in Stellar Spectra, J. Baillaud, 100; Spiral Structure in Star Clusters, Dr. P. ten Bruggencate, 100; Spiral and Structureless Nebulæ, Prof. C. D. Perrine, 170; The Preparation of the "Geschichte des Fixsternhimmels," 203; Two Notable Variable Stars, Dr. W. J. S. Lockyer; Miss M. A. Blagg, 254; Proper Motions of the Hyades, Prof. van Rhijn, 290; Statistics on Stellar Velocities, Prof. F. H. Seares, 390; Studies of Algol Variables, R. S. Dugan, 444; Radiation and Masses of Stars, Prof. H. Vogt, 480; Relative Numbers of Stars of Different Spectral Types, K. G. Malmquist, 514; Prof. La Rosa's Theory on the Cause of Stellar

Variability, Prof. de Sitter; Prof. La Rosa, 550; The Spiral of Nebulæ, Dr. K. Lundmark, 586; The Stars of Type O, Dr. J. S. Plaskett, 622; Stellar Distribution, Prof. H. Shapley, 622; A Remarkable Planetary Nebula in Cassiopeia, J. H. Reynolds, 693; The Effect of Secular Diminution of Mass, Dr. J. H. Jeans, 764; A Study of Stellar Motions, Dr. G. Strömberg, 798; Variable Stars, S. Shinjo and T. Araki, 871; The Distribution of Energy in Stellar Spectra, Dr. C. G. Abbot, 945

Sun:

Sun-spot Activity, 254; Solar Apex and Velocity, B. Fessenkoff and C. Ogrodnikoff, 390; The Total Solar Eclipse of January 24, 1925, R. M. Motherwell, 550

Miscellaneous:

An Anti-Relativity Theory, Prof. La Rosa, 290; The Liverpool Astronomical Society, Annual Report, 1923–1924, 325; Absorption in the Atmosphere, J. Baillaud, 366; The Astronomical Day, 622; Calendar Reform, G. Marvin, 728; Mechanical Analysis of Periodicities, H. de Miffonis, 945

Astronomy, The New, Sir Oliver Lodge, 3

Atlantic Salmon, The, in New Zealand, W. J. Phillipps, 89

Atlantis, The Problem of, L. Spence, 409

Atmosphere: Optical Disturbances in the, A Simple Arrangement for Observing the, C. Gallissot, 523; The Rare Gases of the, Dr. H. Jeffreys, 934

Atmospheric: Electricity, Studies in, No. 65, E. Schweidler; No. 66, W. Schlenck, 184; Ionisation and its Variations, Dr. C. Chree, 918; Nitrogen, Fixation of, by Green Plants, C. B. Lipman and J. K. Taylor, 730; Pollution: Abstracts of Records from Deposit Gauges, 65; Potential Gradient and, Prof. Kerr Grant, 576; Report of the Committee for the Investigation of, 720; The Automatic Measurement of, Dr. J. S. Owens, 330

Atmospherics, R. A. Watson Watt, 918

Atomic: Rays from Heated Salts, Dr. G. C. Schmidt, 800; Structure, Prof. R. A. Millikan, 365; Spectroscopy and, Dr. P. D. Foote, 731

Atoms: and Ethereal Radiations, Dr. R. A. Millikan, 141; and Rays: an Introduction to Modern Views on Atomic Structure and Radiation, Sir Oliver Lodge, 599; Electrons and Radiation, Conditions for Statistical Equilibrium between, P. A. M. Dirac, 772; Non-Hydrogenic, Fine Structures in, A. E. Ruark, F. L. Mohler, and R. L. Chenault, 575; of the same Electron Structure, Some Relations between the Optical Spectra of Different, I., D. R. Hartree, 772; Spectra of some Lithium-like and Sodium-like, D. R. Hartree, 75; The Disintegration of, by α-rays, H. Pettersson and G. Kirsch, 846

Aurora, Potential Gradient and Magnetic Disturbance, C. S. Wright, 466

Australasian Association, the Adelaide meeting of the, E. C. Andrews, 877; Sir Thomas R. Lyle elected president of the next meeting, 877

Australia: Institute of Science and Industry, Second Annual Report of the, 763; the Future of, Tropical Colonisation and, Prof. J. W. Gregory, 314

Australian: Caryophyllæid Cestode, An, T. H. Johnston, 595; Chiromyzini (Diptera), A Revision of the, G. H. Hardy, 452; Diptera: Notes on, No. II., J. R. Malloch, 300; No. III., J. R. Malloch, 452; No. IV., J. R. Malloch, 595; Essential Oils, The Germicidal Values of the Pure Constituents of, A. R. Penfold and R. Grant, 336; Lepidoptera, Revision of, Lassiocampidæ, A. J. Turner, 919; Plants, The Transpiration of Some, with Notes on the Structure of their Leaves, H. W. Wilson, 212; Rainfall, Sunspots and, E. T. Quayle, 523; Resources of Liquid Fuels, R. H. Cambage, 299; Scarabæidæ, Some, A. M. Lea, 300; Timbers: Wood-fibres of Some, investigated in reference to their Prospective Value for Paper-pulp Production, R. T. Baker and H. G. Smith, 190; Weather, Some Periods in, E. Kidson, 524

Automobile Engineers, Institution of, awards of the, 621, 762

Auto-oxidation and Antioxygen Action, C. Moureu, C. Dufraisse, and M. Badoche, 335

Avebury, The Life-work of Lord (Sir John Lubbock), 1834–1913. Edited by his daughter, the Hon. Mrs. Adrian Grant Duff, 239

Avebury's, Lord, Life and Influence, 239

Aviation Motors: Compression in, Experimental Results on Increase of, P. Dumanois, 210; with very High Compression, P. Dumanois, 147

Aviculopecten, from Carboniferous Rocks, Myall Lakes, N.S.W., Eleven New Species of, J. Mitchell, 919

Baade Planet, The, 728; Giacobini and Fatou, 845; Dr. Stracke, 908

Babylonia and Early India, Gadd and Smith, 623

Babylonian Astronomy, Zenith of Primitive, Prof. R. A. Fessenden, 136

Bacillus anthracis (Spore-bearing Form), Attenuation of the Virulence of, E. Ducloux, 559

Backhousia sciadophora (N.O. Myrtaceæ) F.v.M., The Essential Oil of, A. R. Penfold, 336

Bacon's Scheme for a College of Research, Prof. M. H. Liddell, 387

Bagesu, The, and Other Tribes of the Uganda Protectorate: the Third Part of the Report of the Mackie Ethnological Expedition to Central Africa, Rev. Canon J. Roscoe, 745

Bakery Research, Dr. C. Dorée and J. Kirkland, 328

Balanus nubilis, the Operculum of, The Mechanism of Massive Movement of, J. Tait and W. F. Emmons, 919

Ball Lightning, Dr. A. W. Crossley, 10

Ballistic Theory of Light, The, and the Michelson-Morley Experiment, Prof. M. La Rosa, 933

Ballon captif et les aéronefs marins, Étude sur le, Commandant C. Lafon, 566

β-amino-alcohols, The Primary, Corresponding with the General Formula $R . (NH_2) . CH . CR_1R_2(CH_2 . OH)$, P. Billon, 955

Banana, The, 908

Bananas, The Panama Disease of, Prof. S. F. Ashby and others, 208

Band Spectra of Sodium, Potassium and Sodium-potassium Vapours, The Fine Structure of the, H. G. Smith, 30

Bankfield Museum, Halifax, resignation of the keepership by H. Ling Roth, 511

Barogram Analysis in Weather Forecasting, F. Vercelli; L. C. W. Bonacina, 393

Barro Colorado Island, Visit to, W. C. Allee, 98

Basaltic Hornblende from Hungary, The Chemical Composition and Optical Properties of a, M. Vendl, 109

Basque Pyrenees, The Structure of the, P. W. Stuart-Menteath, 552

Bath, Literary and Scientific Institution of, The, 168

Beam System of Radio Telegraphy, The, Senatore Marconi, 359

Beetroot, The Running to Seed of, in the First Year, Munerati, 667

Behind and Before: Two Essays on the Relation of History, Politics and Eugenist Warnings, W. E. Heitland, 569

Beisan from the Air, C. S. Fisher, 909

Belfast, the Queen's University, Bequest to, by J. C. White, 143

Belief, Problems of, Dr. F. C. S. Schiller, 856

Bell's Card of Logarithms and Science Tables, 48

Bellhus, Abington Pigotts, Cambridge, Early Continuity of Occupation at, Dr. C. Fox, 879

Ben Nevis Observatory, The, C. L. Barnes, 810

Berberine, Haworth, Perkin, and Rankin, 589

Bergedorf Observatory, Report of the, 62

Berlin University, Prof. H. Kopff appointed professor of theoretical astronomy in, and director of the Astronomische Recheninstitut, 479

Beryllium II and Carbon IV, The Assignment of Lines and Term Values in, Dr. R. A. Millikan and I. S. Bowen, 380

Bhutan and Southern Tibet, Surveys in, Major F. M. Bailey, 656

Big Game and Pygmies: Experiences of a Naturalist in Central African Forests in Quest of the Okapi, C. Christy, 420

Binary: (2, 1) Forms, The Irreducible System of Concomitants of Two Double, W. Saddler, 919; Solution Equilibrium, Influence of Substitution in the, R. Kremann and H. Drazil, 300
Binocular Vision and the Stereoscopic Sense, R. J. Trump, 75
Biogenen Amine, Die, und ihre Bedeutung für die Physiologie und Pathologie des pflanzlichen und tierischen Stoffwechsels, M. Guggenheim, Zweite Auflage, 927
Biologia Generalis, projected publication of, 622
Biologischen Arbeitsmethoden, Handbuch der, edit. Prof. E. Abderhalden. Abt. XI.: Teil I., Heft 7 (Schluss), Lief. 134, 747
Biology: and Religion, Prof. J. S. Haldane, 468; and Sociology, C. W. Soal, 273; Dr. B. Malinowski, 274; of the Suez Canal, The, Prof. J. Stanley Gardiner, 520
Bird: -marking in America, F. C. Lincoln, 909; Migration, A Sidelight on, Rev. F. S. Briggs, 574; *Notes and News*, Dominion Number, 835; Sanctuary near Farnham, Establishment of a, 169; The, as a Diver: a Contribution to the Natural History of Diving Birds, Dr. J. M. Dewar, 494
Birds: as a Geological Agent: E. A. Martin, 12; Dr. J. W. Evans, 89; British, A Check-list of, with a Short Account of the Status of Each, H. F. Witherby, 308; Flight of, Sir David Wilson-Barker, 645; in their Relations to Man: A Manual of Economic Ornithology for the United States and Canada, Drs. C. M. Weed and N. Dearborn. New edition, 676; of Portugal, The, W. C. Tait, 8; over the High Atlantic Ocean, The Frequency of, P. Jespersen, 281; The Protection of, Conference on, 58
Birmingham: Canon E. W. Barnes appointed bishop of, 200; University: award of doctorates, 28; conferment of honorary degrees; appointments at; openings for graduates leaving, Prof. G. T. Morgan, 71; appointments in, careers to which subjects may lead, and other information, 592; conferment of doctorates, 952
Bismuth: Action of, in Syphilis, Mechanism of the, C. Levaditi, S. Nicolau, Mlles. J. Salgue and R. Schoen, 811; Vapour at High Temperatures, The Fluorescence and Channelled Absorption Spectra of, Prof. A. L. Narayan and K. Rangadhama Row, 645
"Bitumen" in Meteorites, Dr. P. E. Spielmann, 276
Bjerknes's Contribution of 1921 to the Mechanics of the General Circulation, Sir Gilbert Walker, 809
Blair, Robert, Fellowships, award of, to G. Bird and J. d'A. Clark, 180
Blastocystis hominis, Nature of, Major R. Knowles and Assist. Surg. B. M. Das Gupta, 516
Bleaching Reagent, A New, Dr. R. Feibelmann, 625
Blind Cave-fishes, J. R. Norman, 917
Blood: Coagulation, Anti-coagulants, and Hæmolysis, J. W. Pickering and F. E. Taylor, 809; The Examination of, for Gaseous Poisons, E. Kohn-Abrest, 811
Blow-gun in Assam, The, J. H. Hutton, 136
Bohr's Model, The Simultaneous Jumping of Two Electrons in, P. S. Epstein, 703
Bombay University, gift to, by Sir Currimbhoy Ebrahim, 558
Boric Anhydride, Reactivity of, in the Solid State with Metallic Oxides, C. Mazzetti and F. De Carli, 595
Boron: Atom (B III.), The Series Spectra of the Stripped, I. S. Bowen and Dr. R. A. Millikan, 112; Monoxide, The Band Spectrum of, Dr. R. S. Mulliken, 349
Boronia in the Pinnate Section, with a Description of a New Species, E. Cheel, 883
Botanical: Conference, Imperial, F. T. Brooks, 293; Survey of the Empire, The Best Means of promoting a Complete, Dr. A. W. Hill and others, 293
Botany, Practical, Rai Bahadur K. Rangachari, 306
Boxer Indemnity, The: Dr. R. P. Scott, 726; and Chinese Education, 777
Boyle's Law, New Design for Apparatus to Measure the Coefficient of Deviation from, and the Determination of this Coefficient for Acetylene, J. T. Howarth and F. P. Burt, 883
Brachycephalic Skull, The, Prof. F. G. Parsons, 445
Brackish-water: Actinian from Madras, A, H. S. Rao, 183; Fauna of Spain, Additions to the, E. Rioja, 204
Brain and Golf, The, Some Hints for Golfers from Modern Mental Science, C. W. Bailey; and a Chapter on Theory and Practice by B. Darwin, 271
Brass: Rod, The Extension of, by the Inverted Process, R. Genders, 487; Season-cracking of, G. Masing, 767; Tubes, A Method for measuring Internal Stress in, R. J. Anderson and E. G. Fahlman, 487
Brazil, Weather on the Coast of, Wireless Reports of, 836
Breast, The Diseases of the, W. H. Evans, 120
Bretonneau: His Life and Work, Dr. J. D. Rolleston, 653
Brewing, Institute of, Journal of the, Collective Index of the, 1911 to 1923, W. H. Bird, 677
Brinell Hardness of Copper, Effect of Progressive Cold-rolling on the, H. Moore, 522
Bristol Geology and Geography: for the Use of School Teachers and Others, Prof. S. H. Reynolds, 821
British: Actiniaria, T. A. Stephenson, 752; Antarctic Expedition, 1910–1913. Meteorology. Vol. 3: Tables, Dr. G. C. Simpson, 853; Association: The Toronto Meeting of the, 130, 138, 247; Message from the Prince of Wales, 199; 1925, Prof. H. Lamb elected president of the next meeting, 248; Report on the Distribution of Government Publications, 251; and the International Mathematical Congress, The Trans-Canadian Excursion of the, 768; A Totem Pole representing the, Sir Richard Paget, 905; Birds, A Practical Handbook of, edited by H. F. Witherby. 2 vols., 119; Cast Iron Research Association, new laboratories of the, 134; Desmidiaceæ, A Monograph of the, the late W. West and the late Prof. G. S. West, Vol. 5, by Dr. Nellie Carter, 783; Dirigible Programme, The, 842; Dyestuffs Industry: The, Prof. W. M. Gardner, 113; Corporation, The, Prof. W. M. Gardner; Dr. Levinstein, 592; Electrical and Allied Manufacturers' Association, award and renewals of scholarships, 771; Empire: Exhibition: Exhibit of Pure Science at the, Dr. J. S. Owens, 12; The Agricultural Exhibit at the; Meteorological Exhibits at the, 60; Some Geographical Aspects of the, 128; The Chemical Exhibits, etc., at the, Dr. E. F. Armstrong, 133; Exhibits of the Imperial Institute, and Thomas Firth and Sons, Ltd., at the, 442; Museums and the, Dr. H. Bolton, 149; Science and the, 526; Flora: Handbook of the, a Description of the Flowering Plants and Ferns Indigenous to, or Naturalised in, the British Isles; for the Use of Beginners and Amateurs, G. Bentham. Revised by Sir J. D. Hooker. New edition revised by Dr. A. B. Rendle, 379; Glues and Chemicals, Ltd., Exhibition of, 584; Institute of Radiology, Prof. S. Russ, 770; Medical Association at Bradford, The, 178; Meteorological and Magnetic Year Book, 1915. Part 5: Réseau Mondial, 1915, 747; Museum: J. Ramsay MacDonald and Sir David Prain elected trustees of the, 906; Bill, The, Sir Hercules Read, 167; (Natural History): E. E. Austen appointed deputy keeper in the Department of Entomology, 20; Staff Association, Summer Conversazione of the, 99, 763; picture post-cards of the, 133, 388, 738; new exhibits at the, 655; Catalogue of Rhopalocera, Part I., H. D. Riley and A. G. Gabriel, 763; Pharmaceutical Conference, The, 201
Broadcasting: of Science Talks from the Birmingham Station, 252; The Present Position and Some Possible Future Developments of, Reith, 618
Bröggerites, The Composition of, etc., W. Riss, 184
Bromine: The Absorption Spectrum of, P. Bovis, 31; X-radiation, Reflection of Characteristic, by a Crystal of Potassium Bromide, S. K. Allison and W. Duane, 559
Bronze, High-tin, Effect of Casting Temperature and Heat-treatment on the Physical Properties of a, F. W. Rowe, 522
Brooklyn Institute of Arts and Sciences, Museum of the, Additions to the, 763
Brown: Bast Disease of Rubber Trees, A. Sharples and J. Lambourne, 838; Corona, The, and the Diameters of Particles, L. F. Richardson, 666
Browne, Sir Thomas, Kt., M.D., A Bibliography of, G. Keynes, 678

Brussels, University of: Applied Science at the, 915; the foundation-stone of the new buildings of the, laid by Prince Leopold, 808
Bucherer's Experiments on e/m, Interpretation of the Results of, T. Lewis, 882
Buenos Aires, National Museum of Natural History at, Prof. M. Doello-Jurado appointed director of the, 762
Bufo, The Development of the Otocysts of, Increase of the Surface and Increase of the Volume during, S. Ranzi, 595
Burthogge, Richard, The Philosophical Writings of, edited by Margaret W. Landes, 822
Busk Studentship in Aeronautics, J. C. Stevenson appointed to the, 260

Cacao: Budded, Branching in, S. C. Harland and R. G. Parga, 516; Fruit Production in, Prof. S. C. Harland, 446
Cactaceæ, The, Descriptions and Illustrations of Plants of the Cactus Family, N. L. Britton and J. N. Rose. Vol. 4, 424
Cactus Family, The, N. E. Brown, 424
Cadmium: Tellurium, and Bismuth, The Mass-spectrum of, Dr. F. W. Aston, 717; The Silicate Compounds of, A. Duboin, 739
Calamities, The Distribution of, 367
Calcium Sulphate Cements, The Mechanism of Setting of, C. L. Haddon, 182
Calcul tensoriel et au calcul différentiel absolu, Introduction au, Prof. G. Juvet, 339
Calculation by Deficients, Rev. C. A. B. Brockwell, 296
Calculus of Observations: The, a Treatise on Numerical Mathematics, Prof. E. T. Whittaker and G. Robinson, 377; Practical, for Home Study, Prof. C. I. Palmer, 856
Calcutta "Poverty Problem Study" Organisation, formation of a Limited Liability Company in connexion with the, 260
Calendar Reform, G. Marvin, 728
Cambridge: Biographies, 459; Philosophical Society, election of officers and council, 797; Readings in the Literature of Science: being Extracts from the Writings of Men of Science to illustrate the Development of Scientific Thought. Arranged by W. C. D. Whetham and his daughter Margaret D. Whetham, 404; Region: The Archæology of the, a Topographical Study of the Bronze, Early Iron, Roman and Anglo-Saxon Ages, with an Introductory Note on the Neolithic Age, Dr. C. Fox, 494; Regional Survey of, 494; Solar Physics Observatory at, Annual Report of the, 480; University: appointments in, 71; Dr. G. H. F. Nuttall re-elected Quick professor of biology; D. L. Burn elected Wrenbury scholar in economics, 180; award of research studentships, 180; a Trinity College Research Studentship awarded to J. Ratner; the Dunning Scholarship to L. St. Clair Broughall, and a Dominion and Colonial Exhibition to J. B. Williams, 208; and the Royal Commission, Provisional Scheme, 259; W. S. Thatcher appointed censor of the non-collegiate students, 260; gift to the School of Pathology, E. Gates, 395; entry of Prof. A. C. Seward as Vice-Chancellor, 557; the outlook, 592; Dr. T. M. Cherry and J. H. Quastel elected to fellowships at Trinity College, 593; offer of books and money by Mrs. Marshall; T. A. Carroll appointed assistant director of the Solar Physics Observatory; G. A. Reay, W. W. Grave and P. A. Taylor elected to research studentships at Emmanuel College, 629; gift to the Sedgwick Museum by Lady Teall; Dr. M. B. R. Swann reappointed demonstrator of pathology; F. P. Ramsey elected to a fellowship at King's College, 665; T. R. B. Sanders elected a fellow of Corpus Christi College; A. M. Binnie awarded the John Winbolt prize in engineering, 700; D. R. Hartree and E. A. Watkins elected fellows of St. John's College, 735; H. E. Tunnicliffe and N. J. T. M. Needham elected fellows of Gonville and Caius College; the John Bernard Seely prize awarded to W. A. Johnson; Dr. D. H. S. Cranage appointed secretary of the Board of Extra-mural Studies and Rev. J. W. Hunkin secretary of the General Board of Studies, 771; G. T. Griffith awarded the Adam Smith prize, 807; The Engineering Department of, 833; F. Balfour Browne appointed University Lecturer in Zoology, 842; Report of the Botanic Garden Syndicate; the future award of the John Bernard Seely prize, 915; G. Stead appointed University lecturer in physics as applied to Medical Radiology; Dr. A. J. Copeland appointed assistant to the Downing professor of medicine; the Gordon Wigan prize awarded to E. H. Warren, 952
Cameroons, Iron Working in the, L. W. G. Malcolm, 481
Canada: Arctic, Geology and Geography of, J. J. O'Neill and others, 766; Dominion Observatory at Ottawa, R. M. Stewart appointed director of the, 134; Royal Society of, Prof. J. C. McLennan elected president of the, 20
Canadian Eclipse Expedition to Wallal, 1922, The, C. A. Chant and R. K. Young, 135
Cancer: How it is caused, how it can be prevented, J. Ellis Barker, 496; concerning the review of, J. Ellis Barker, 692; its Causation, Prevention and Cure, Dr. J. Harger, 855; Paraffin, Dr. A. Scott, 167; Research: Fund, Imperial, Annual Meeting of the, 167; at the Middlesex Hospital, 1900–1924: Retrospect and Prospect, edited by W. S. Handley, 533
Canned Foods in Relation to Health, Dr. W. G. Savage, 120
Cantabrigienses, Alumni: a Biographical List of all known Students, Graduates, and Holders of Office at the University of Cambridge, from the Earliest Times to 1900. Compiled by Dr. J. Venn and J. A. Venn. Part 1 (in 4 vols.). Vol. 3, 459
Cape Observatory, Report of the, Dr. H. Spencer Jones, 21
Capillary Action: Transpiration, Sir W. Galloway, 933
Capital as a Factor in Evolution, Sir Arthur Keith, 943
Carbon: at High Temperatures, The Vapour Pressure of, H. Kohn and M. Guckel, 695; Atom in Crystalline Structure, The, Sir William Bragg, 862; Di-sulphide, The Phosphorescent Flame of, Prof. H. B. Dixon and W. F. Higgins, 774; Monoxide: Poisoning, Apparatus to facilitate the Use of an Oxygen-carbon-dioxide Mixture on the Treatment of, Prof. H. Briggs, 110; The Absorption of, by Cuprous Sulphate in the Presence of Sulphuric Acid, A. Damiens, 147; The Estimation of, P. Lebeau and C. Bedel, 262; Solid, The Vapour Pressure of, J. J. van Laar, 210; Steels, Dendritic Structures in, T. Ishiwara, 948; The Estimation of, by the Argentosulphochromic Method, L. J. Simon, 845
Carex remota and *C. divulsa*, A Hybrid between, C. E. Salmon, 109
Carnegie Corporation of New York, Reports of the, 916
Carved Stones in the Dayang Valley, Some, J. H. Hutton, 372
Caryophyllæus from Siluroid Fishes of the Sudan, Some Remarkable, Dr. W. N. F. Woodland, 917
Cassiopeia, A Remarkable Planetary Nebula in, J. H. Reynolds, 693
Cast Iron: Research Association, Annual Meeting of the, Sir John Dewrance elected president, 797; The Phosphide Eutectic in, Dr. F. Rogers, 275
Castner-Kellner Alkali Co., Ltd., issue of pamphlets by the, 290
Catalan Studies, The Institute of, at Barcelona, J. Langdon-Davies, 538
Catalysis, Heterogeneous, W. E. Garner, 932
Cathode Dark Space, Action of a Transverse Magnetic Field on the, Dr. A. G. Schulze, 102
Catopterid Fish, A New, from the Keuper of Nottingham, H. H. Swinnerton, 74
Cattle Breeding Conference, The Scottish, Dr. F. A. E. Crew, 206
Caucasus Isthmus, The Deluged Civilisation of the, Prof. R. A. Fessenden, 892
Cave Bears, The Development of the Base of the Skull in, from the Drachenhöhle near Mixnitz, K. Ehrenberg, 183
Cell: Growth, Mechanism of, F. Weber, 258; -wall Formation, Prof. R. R. Gates, 788
Cells, Crystals and, 233
Celluloid, Molecular Dimensions of, V. P. Barton and F. L. Hunt, 861
Cercaria, A New, from Northern India, Dr. B. Sopankar, 326

Ceremonial Banquets, F.R.S., 12
Ceylon, Botanical Notes from, I. Petch and others, 23
Chalkones and Hydrochalkones, V. Tognazzi, 631
Chalky Boulder Marl at Hastings, W. J. Lewis Abbott, 312
Charadriiformes, The Literature of the, from 1894–1924: with a Classification of the Order, and Lists of the Genera, Species, and Sub-species, Dr. G. C. Low, 428
Charophyta collected during a recent visit to Madagascar, T. B. Blow, 110
Chatham Islands, The Morioris of, H. D. Skinner, 295
Chemical: Change, Effect of Motion on, Duparc and Molly, 625; Apparatus and Plant Production, L. M. G. Fraser, 388; Constants, A. Schidlof, 589; Encyclopædia: a Digest of Chemistry and Chemical Industry, C. T. Kingzett. New edition, 403; Engineers, Institution of, Transactions of the. Vol. I., 1923, 605; Evidence in Archæology, The Value of, A. Lucas, 288; Industry: Co-operation in the, Sir Max Muspratt and Sir John Brunner, 200; The Heavy, R. Furness, 491; Reactions: at High Pressures, W. Rintoul, 898; Very Rapid, Further Developments in the Technique for the Measurement of the Velocity of, Dr. H. Hartridge and F. J. W. Roughton, 75; Societies, Organisation in, Dr. M. W. Travers, 501, 682; J. E. Marsh, 682; Prof. J. C. Philip, 609; Analysis: Instrumental Methods of, A Course of Instruction in, Prof. W. N. Lacey, 713; Lunge and Keane's Technical Methods of. New edition. Edited by Dr. C. A. Keane and P. C. L. Thorne. Vol. I., 640; of Blood, Practical, a Book designed as a Brief Survey of this Subject for Physicians and Laboratory Workers, Prof. V. C. Myers. Second edition, 85
Chemicals, Fine, T. W. Jones, 491
Chemist: as Propagandist, The, 491; The, and the Fermentation Industries, J. L. Baker, 735
Chemistry: A Third Year Experimental, W. H. Crabb, 426; and the State, Sir Robert Robertson, 227; Applied: Prof. I. D. Garard, 929; A Dictionary of, Sir Edward Thorpe, assisted by eminent contributors. New edition. Vol. V., 532; in Peace and War, 113; Progress of, Reports of the. Vol. VIII., 1923, 403; Colloid, Wisconsin Lectures, Prof. The. Svedberg, 153; during this Century, Some Developments in, Prof. J. A. Wilkinson, 802; Examples in, Dr. W. W. Myddleton, 929; for Dental Students, Prof. H. C. Smith and Rachel M. Smith. New edition. 2 vols., 677; for Schools, A First, W. H. Hewitt and S. T. E. Dark, 571; in the Twentieth Century: an Account of the Achievement and the Present State of Knowledge in Chemical Science, 5; Laboratory Experiments in, to accompany Black and Conant's "Practical Chemistry," N. H. Black, 346; Modern, Prof. A. Findlay, 5; of the Rarer Elements, Prof. B. S. Hopkins, 375; Russia's Contribution to, Some Aspects of, Prof. W. P. Wynne, 662; The Co-operation of the Scientific and Industrial Branches of, W. J. U. Woolcock, 584; The Outlook in, Sir William Pope, 133; and the State, Sir Robert Robertson, 383
Chemists: and Physics, Sir William Pope, 690; and their Work, Dr. S. Miall, 491
Chemotherapy, Progress and Prospects in, Dr. H. H. Dale, 230
Cheyenne Indians, The: their History and Ways of Life, G. B. Grinnell. 2 vols., Dr. A. C. Haddon, 188
Childbirth Customs among the Indians of New Mexico, Dr. E. C. Parsons, 623
Chilina, New Species of, W. B. Marshall, 872
Chimæras Dire, Dr. W. T. Calman, 11; Transplantation of Heads of Insects, Prof. H. Przibram, 347; Dr. W. T. Calman, 467
Chimica generale ed applicata all' industria, Trattato di, Prof. E. Molinari. Vol. I., Chimica inorganica. Parte prima. Quinta edizione, 605
Chimie physique, Précis de, H. Vigneron, 676
China: Indemnity Bill, The, 301; The Early Ceramic Wares of, A. L. Hetherington. Popular and abridged edition, 342; The Iron Ores of, 333
Chinese: Education, The Boxer Indemnity and, 777; Floods, The, 479; Growth of, Dr. S. M. Shirokogoroff and Dr. V. B. Appleton, 799; Plants, New, H. Handel-Mazzetti, 846; Pottery, W. Burton, 342; Turkistan and Kansu, Memoir on Maps of, from the Surveys made during Sir Amel Stein's Explorations, 1900–1, 1906–8, 1913–15, with Appendices by Major K. Mason and J. de Graaff Hunter, 338
Chloric Acid, The Neutralisation of, by the Alkalis, followed by Means of Viscosimetry, L. J. Simon, 774
Chlorine, an antiseptic of a compound containing, 96
Chloroform, The Chlorination of, H. Gault and R. Truffault, 523
Chlorophyll: Extracts, The Decomposition of, A. Mailhe, 32; Grains in the Plant Cell, Change of Position of the, G. Senn, 666
Chloropicrin, Action of Light on Solutions of Certain Organic Substances in, A. Piutti and P. Badolato, 595
Christian Science, The Meaning of, C. W. J. Tennant, 907
Chromic Acid, The Composition of, H. T. S. Britton, 589
Chromite, The Oxidation of, and the Preparation of Chromates, B. Bogitch, 210
Chromosomes, Species and, Prof. R. R. Gates, 353
Church, The, and Disease, Science, 741
Cinematograph: in Anthropology, The, 807; in Education, W. M. Webb, 297; Report of the Imperial Education Conference Committee on, 298
Circles, The Graduation of, J. A. Smith, 523
Circumnavigation of the Earth by Aeroplane, 439
Civil Engineering, An Introduction to the Practice of, E. E. Mann, 714
Civil Engineers, Institution of: awards of the, 513, 549; Sir J. J. Thomson and Dr. W. C. Unwin elected honorary members of the, 870
Civilisation: History of, H. Frankfort, 837; The Growth of, W. J. Perry, 272
Cladium mariscus in Norway, Dr. Holmboe, 765
Clay, Physical Properties of, A. S. E. Ackermann, 124
Clepsydræ, Ancient, R. W. Sloley, 623
Climate, Adaptation of Variety to, R. A. Fisher, 210
Climatology, Objective and Subjective, 44
CN Molecule, Electronic States of the, Dr. R. S. Mulliken, 858
Coal: and Electric Power, 417; and Power, the report of an enquiry presided over by the Rt. Hon. D. Lloyd George, 265; Destructive Distillation of, E. V. Evans, 696; Dust Explosions, Prof. H. B. Dixon, 838; Mining Industry, Problems of the, Prof. H. Louis, 265; Mining, The Human Factor in, Prof. J. S. Haldane, 598; The Economic Utilisation of, H. E. Weaver, 368; The Low Temperature Carbonisation of, 441
Coast Defence Works, Dr. J. S. Owens, 328
Cobalt Ores, E. Halse, 8
Cocaine Hydrochloride, The Variation of the Anæsthetic Power of, as a Function of the Proportion of Hydrogen Ions, J. Régnier, 371
Cochlea, The Mechanism of the: a Restatement of the Resonance Theory of Hearing, G. Wilkinson and Dr. A. A. Gray, 493
Cock, The Domestic, Experimental Bipartite Gynandromorphism in, Pezard, Sand, and Caridroit, 956
Coco-palms, Water Absorption by, R. B. Espino and J. B. Juliano, 588
Cod and Cod Fishery, W. C. Smith; Prof. J. Johnstone; Prof. J. Johnstone and A. Scott, 485
Coffee Culture, Grafting in, Dr. P. J. S. Cramer, 557
Coherer, The Use of the, to Investigate Adsorption Films, W. G. Palmer, 31
Coke, Dry Cooling of, in Gasworks Practice, 137
Coleoptera, Observations on, H. Donisthorpe and others, 729
Colloid Chemistry: Dr. E. K. Rideal, 798; Collective and Individual Effort in, E. Hatschek, 781; Wisconsin Lectures, Prof. The. Svedberg, 153
Colloidal: Behavior, The Theory and Application of, contributed by the Foremost Authorities in each Division of the Subject. Edited by Dr. R. H. Bogue. 2 vols., 781; Systems, Properties of, 672

Colloids: and Mineral Waters, E. Henrijean and W. Kopaczewski, 811; Chemistry of, P. C. L. Thorne, 153; The Effects of Dilution on, W. Kapaczewski, 667
Colombia, A Skull of Papuan Type from, Dr. R. Verneau, 656
Colorado: Mollusca of, J. Henderson, 624; University, Summer School of, 260
Colour: Nomenclature, Dr. L. C. Martin, 790; Photographs, Electrical Transmission of, 478; The Quest for, a Short Survey of the Story of Colour in Relation to Man's Needs and Achievement, Dr. A. T. de Mouilpied, 491; Vision: An Introduction to the Study of, Sir John Herbert Parsons. New edition, 341: Theories of, Prof. W. Peddie, 341
Colours, Stains, and Dyes, Prof. J. F. Thorpe, 125
Comet: New, 1924 *c*, 480; Finsler's, 1924 *c*, 514
Comets: 586; Finsler's and Encke's, 655; Orbits of, 514; Skjellerup's and Grigg's, Crawford and Meyer, 871
Commerce, The Goal of, G. G. Chisholm, 694
Compressible Fluids, The Flow of, Treated Dimensionally, W. N. Bond, 108
Compton: A. H., Effect, Spectrographic Researches on the, A. Dauvillier, 111; And Duane Effects, The, J. A. Becker, 703
Congo: Across the Great Craterland to the, a Sequel to "The Wonderland of the Eastern Congo," Dr. T. A. Barns, 785; Fetish, A, H. V. Hall, 551
Conics, Analytical, Dr. D. M. Y. Sommerville, 495
Coniferæ, An Endotropic Fungus in the, Prof. F. J. Lewis, 860
Conifers, Carbon Assimilation in, G. Stälfelt, 552
Continuity, President of the Board of Education, 843
Continuous Current Circuits and Machinery, Profs. J. H. Morecroft and F. W. Hehre. Vol. I., 678
Contraception (Birth Control): Its Theory, History, and Practice: a Manual for the Medical and Legal Professions, Dr. Marie Carmichael Stopes, 601; The Technique of, Sir G. Archdall Reid, 601; Dr. Marie C. Stopes, 719
Conularia in the Carboniferous Limestone of North Wales, J. W. Jackson, 954
Cooling Power of the Air in Trains, Trams, and Buses, The, Leonard Hill, with the co-operation of M. Brad, 246
Co-ordination, Studies of. Pt. I., Helen S. French and Prof. T. M. Lowry, 773
Copper: and Mercury Salts in Plants, The Poisonous Action of, H. Lundegårdh, 799; and Silver, Low-voltage Arc Spectra of, Dr. A. G. Shenstone, 501; Arc, Spectrum Observations on the, F. Simeon and E. S. Dreblow, 751; Effects of Impurities on. Pt. II., D. Hanson and Grace W. Ford, 488; Low-voltage Arc Spectra of, Dr. A. G. Shenstone, 934; -silicon-aluminium and other Aluminium Alloys, Comparative Results on, E. H. Dix, Jr., and A. J. Lyon, 487; The Catalytic Action of. Pt. IV., W. G. Palmer, and F. H. Constable, 31
Cordierite in a Cordierite-gneiss from Madura District, Madras, M. S. Krishnan, 774

CORRESPONDENCE.

Abney Sectors in Photometry, G. F. Wood, 467; F. E. Cady, 683
Absorption of Vapours of Various Liquids by Cotton, R. C. Brimley, 432
Absorption Spectra of Some Metallic Vapours, Prof. A. L. Narayan, G. Subrahmaniam, D. Gunnaiya, and K. Rangadhamarao, 194
Achromatism in Telescopes, The Choice of Wave-lengths for, Prof. T. Townsend Smith, 536; Lt.-Col. J. W. Gifford, 644
Acoustic Method of Depth Sounding for Navigating Purposes, Early Canadian Experiments on the, Prof. L. V. King, 122
Actiniaria, British, T. A. Stephenson, 752
Aeroplanes, The Forces which lift, Major A. R. Low, 719
Agricultural Research, Cantab, 465; Sir E. J. Russell, 641
Albino Mice, Congenital Eye Anomalies in, E. S. Pearson, 433
Aluminium and Magnesium, Series in the Spectra of, in the Extreme Ultra-violet, Prof. T. Lyman, 641
Ancient Flint Implements at Cromer, Further Discoveries of, J. Reid Moir, 242
Anomalous Adsorption, J. B. Speakman, 352
Aquarium Technique, Dr. Monica Taylor, 752
Argon, Negative and Doubly Charged Positive Ions in, H. A. Barton, 826
Art-forms in Nature, Sir T. A. Cook, 52
Atlantic Salmon in New Zealand, The, W. J. Phillipps, 89
Atmospheric Pollution, Potential Gradient and, Prof. K. Grant, 576
Atoms, Non-Hydrogenic, Fine Structures in, A. E. Ruark, F. L. Mohler, and R. L. Chenault, 575
Aurora, Potential Gradient and Magnetic Disturbance, C. S. Wright, 466
Ball Lightning, Dr. A. W. Crossley, 10
Ballistic Theory of Light, The, and the Michelson-Morley Experiment, Prof. M. La Rosa, 933
Beryllium II. and Carbon IV., The Assignment of Lines and Term Values in, Dr. R. A. Millikan and I. S. Bowen, 380
Bioclimatic Law, Notes on the, Dr. A. D. Hopkins, 608
Biology and Sociology, C. W. Soal, 273; Dr. B. Malinowski, 274
Bird Migration, A Sidelight on, Rev. F. S. Briggs, 574
Birds as a Geological Agent, E. A. Martin, 12; Dr. J. W. Evans, 89; Flight of, Sir David Wilson-Barker, 645
Bismuth Vapour at High Temperatures, The Fluorescence and Channelled Absorption Spectra of, Prof. A. L. Narayan and K. Rangadhama Row, 645
"Bitumen" in Meteorites, Dr. P. E. Spielmann, 276
Boron Monoxide, The Band Spectrum of, Dr. R. S. Mulliken, 349
Burials, Contracted, A Possible Origin of, Dr. H. O. Forbes, 535
Cadmium, Tellurium, and Bismuth, The Mass-Spectra of, Dr. F. W. Aston, 717
Cancer, The Causation of, J. Ellis Barker; The Reviewer, 644
Capillary Action: Transpiration, Sir W. Galloway, 933
Cast Iron, The Phosphide Eutectic in Dr. F. Rogers, 275
Catalan Studies, The Institute of, at Barcelona, J. Langdon-Davis, 538
Catalysis, Heterogeneous, W. E. Garner, 932
Celluloid, Molecular Dimensions of, V. P. Barton and F. L. Hunt, 861
Cell-wall Formation, Prof. R. R. Gates, 788
Ceremonial Banquets, F.R.S., 12
Chalky Boulder Marl at Hastings, W. J. Lewis Abbott, 312
Chemical: Reactions on High Pressures, W. Rintoul, 898; Societies, Organisation in, Dr. M. W. Travers, 501, 682; Prof. J. C. Philip, 609; J. E. Marsh, 682
Chimæras Dire: Transplantation of Heads of Insects, Dr. W. T. Calman, 11, 467; Prof. H. Przibram, 347
Clay, Physical Properties of, A. S. E. Ackermann, 124
CN Molecule, Electronic States of the, Dr. R. S. Mulliken, 858
Contraception, The Technique of, Dr. Marie C. Stopes, 719
Copper Arc, Spectrum Observations on the, F. Simeon and E. S. Dreblow, 751
Crepidula fornicata, English Enemies of the American Slipper-limpet, Dr. J. H. Orton, 312
Cyclones, The Cause of, A. H. R. Goldie, 786
Drift Indicator, A New, J. N. Carruthers, 718
Earth Tides and Ocean Tides, Dr. J. W. Evans, 49; and Local Geology, W. D. Lambert, 572; Dr. J. W. Evans, 749
Edible Earth from Travancore, D. Hooper, 789
Electric: Charges by Friction, H. E. Goodson, 159; Discharge, A Rotational "Fatigue" Effect of the, J. Taylor, 382
Electrical Properties of Thin Films, Dr. A. Frumkin, 158
Electrodeless Discharge, The, Dr. P. D. Foote and A. E. Ruark, 750
Elements, Transformations of, Prof. A. Smits, 609
Endotropic Fungus in the Coniferæ, An, Prof. F. J. Lewis, 860

Eolithic Ornament and Art, J. Reid Moir, 861
"Evolution: at the Crossways," H. Reinheimer; G. P. B., 611; Mendelism and, J. S. Huxley, 464; J. T. Cunningham, 9, 537; C. Dover, 10
Exhibit of Pure Science at the British Empire Exhibition, Dr. J. S. Owens, 12
Explosions, Study of, Sir Oliver Lodge, 10; P. J. Ryle; Dr. H. Jeffreys, 123
Five- (and Six-) point Support: "Right as a Trivet," Sir H. Greenhill, 463; Dr. J. W. French, 575
Flowering and Growth, Effect of Length of Day on, M. A. H. Tincker, 350
Frequency Curves of Genera and Species, G. Udny Yule, 10
Gases of the Atmosphere, The Rare, Dr. H. Jeffreys, 934
Gelatin, The Shrinkage of, Prof. D'Arcy W. Thompson, 576; E. Hatschek, 643
Geometrical Constraint, The "Hole, Slot and Plane," W. N. Bond, 502
Germanium and its Derivatives, Prof. G. T. Morgan and Dr. H. D. K. Drew, 194
Geum urbanum × *rivale*, The Supposed Constancy of the Hybrid between the Common and the Water Avens, Prof. F. E. Weiss and D. Rosén, 500
Glycogen, The Molecular Weight of, Dr. W. Fearon, 752
Gravity Measurements in Deep Water, Prof. J. Joly, 538
Growth and Senescence, Theories of, Prof. T. B. Robertson, 896
Growth-ratios, Constant Differential, and their Significance, J. S. Huxley, 895
Hearing: The Resonance Theory of, J. Keen, 572; G. Wilkinson, 719; The Theory of, Sir R. A. S. Paget; G. Wilkinson, 87; Prof. E. W. Scripture, 194; Dr. H. Hartridge, 243
Helium, Mercury and, J. J. Manley, 861
Herring Scales, Growth-rings of, H. J. Buchanan-Wollaston, 348
"Hole, Slot and Plane," Geometrical Constraint, The, W. N. Bond, 502
Hydrogen: Ion Concentration, Solubility of Phosphates in Relation to, Dr. W. R. G. Atkins, 275; Ions in, Different Types of, Dr. H. D. Smyth, 124; Lines in Giant Stars, A Possible Explanation of the Behaviour of the, Prof. K. T. Compton and Prof. H. N. Russell, 86
Indian: Institute of Science, The, Dr. M. W. Travers, 156; Prof. J. Thorpe, 157; Prof. S. S. Bhatnagar, 538; Ocean, Gravity Observations on the, and the Results of their Isostatic Reduction, W. Bowie, 930
Inert Gases on the Earth, The Rarity of the, Dr. F. W. Aston, 786
Insect Fauna of an Indian Island, The, C. Dover, 351
Insects, Heads of, Transplantation of, J. T. Cunningham, 124; Prof. H. Przibram, 347
Ionised Potassium, On the Spectrum of, in connexion with the Red and Blue Spectrum of Argon, T. L. de Bruin and Prof. P. Zeeman, 352
Iron and Steel, Specific and Latent Heats of, A. Mallock, 429
Kalahari Desert, Former Fertility of the, Prof. E. H. L. Schwarz, 312
Labour, Science and, Major A. G. Church, 89
Lake Victoria and the Flow of the Yala River, Dr. G. D. Hale Carpenter, 311; N. L. Silvester; C. E. P. Brooks, 536
Leaf-mould, Prof. J. B. Farmer, 87
Lightning, Photographs of, Dr. G. C. Simpson, 433
Line and Band Spectra, The Isotope Effect in, Dr. R. S. Mulliken, 89
Liquid Crystals—Soap Solutions and X-rays, Prof. J. W. McBain, 49
Lithobius, The Oogenesis of, S. D. King, 52; Vishwa Nath, 159
Low-voltage Arc Spectra of Copper and Silver, A. G. Shenstone, 501, 934
Low Voltage Arcs, Explanation of Abnormal, Prof. K. T. Compton and C. H. Eckart, 51
Lucerne (*Medicago sativa*), Seed Inoculation of, and its Relation to the Motility of the Nodule Organism in Soil, H. G. Thornton and N. Gangulee, 932
Luminescence of Solid Nitrogen and the Auroral Spectrum, Prof. L. Vegard, 715
McLeod Gauge, A Substitute for the, H. A. Fleuss, 12, 467; Dr. N. R. Campbell, J. W. Ryde and B. P. Dudding, 276, 467
Magnetic Fields, very Intense, The Production of, Dr. T. F. Wall, 432, 898
Mars, The Temperature of, C. T. Chase, 934
Mathematics at British Universities, A Beginner in Relativity, 194
Mendelism: and Evolution, J. T. Cunningham, 9, 537; C. Dover, 10; J. S. Huxley, 464
Mercury: and Bismuth, Isotopes of, and the Satellites of their Spectral Lines, Prof. H. Nagaoka, 245; and Helium, J. J. Manley, 861; into Gold, The Reported Transmutation of, Prof. F. Soddy, 244; Line λ 2270 A., On the, Dr. T. Takamine and M. Fukuda, 382
Metallic Vapours, Mixed, Absorption Spectra of, S. Barratt, 827
Meteorites, "Bitumen" in, Dr. P. E. Spielmann, 276
Microseisms and Storm Forecasts, E. P. Harrison, 645
Molecules, The Structure of, in Relation to their Optical Anisotropy, Prof. C. V. Raman, 49
Naphthalene, The Use of, as a Fumigant in the Control of Red Spider and other Pests in Cucumber Houses, E. R. Speyer, 193
Nebulæ, Spiral and Structureless, J. H. Reynolds, 431
Nebulium Lines, Spectral Theory and the Origin of the, S. Rosseland, 859
New Plant Virus Disease, The Transmission of a, by Insects, H. H. Storey, 245
New Zealand, The Atlantic Salmon in, W. J. Phillipps, 89
Nitrogen: Active, Prof. R. T. Birge, 642; Lord Rayleigh, 717; and Uranium, Dr. P. D. Foote, 789
Ocean Tides, Earth Tides and, Dr. J. W. Evans, 49; and Local Geology, W. D. Lambert, 572; Dr. J. W. Evans, 749
O. edulis, Sex Change and Breeding in the Native Oyster, Dr. J. H. Orton, 191
Oligochaet, A Rare British, Rev. H. Friend, 124
Optical: Records and Relativity, Prof. H. Wildon Carr; Prof. C. Lloyd Morgan, 681; Separation and Atomic Numbers, A. C. Menzies, 861
Orchis Fuchsii (Druce), a Valid Species of Orchidaceæ? Is, Dr. H. O. Forbes, 610
Ores, The Origin of, Dr. R. H. Rastall, 12
Organ-pipes of Unusual Shapes, On the Vibrations of Air in, J. A. Aldis, 309; W. E. Benton, 573, 787; Dr. E. T. Paris, 465
Parabola, Approximate Rectification of the, J. H. Hardcastle, 159
Pearl Mussel, Life History of the, Prof. A. E. Boycott, 276
Phenological Research, International Co-operation in, J. E. Clark, I. D. Margary and R. Marshall, 607
Photographic Plates, The Uniform Development of, G. M. B. Dobson and D. N. Harrison, 752
Photometry, Abney Sectors in, G. F. Wood, 467
Plant Biology, Some Poetic Allusions to Phenomena of, Dr. W. R. G. Atkins, 158
Polarised Light and Starch Content of Plants, E. Sidney Semmens, 719
Polonium, The Anomalous Emission of α-Particles from, Dr. R. W. Lawson, 121
Potential Gradient and Atmospheric Pollution, Prof. K. Grant, 576
Prehistoric Egyptian Vases, The "Ship-designs" on, Dr. H. O. Forbes, 499; Sir Flinders Petrie, 645
Pressure Shift, Temperature Class, and Spectral Terms, Relation between, M. A. Catalán, 192
Primitive American Decorative Art, Interpretations of, G. C. Robson, 381; Dr. H. O. Forbes, 716
Probability Integral, An Approximation to the, Prof. H. C. Plummer, 610
Pyramid and Prophecy, D. Davidson, 750; The Reviewer, 751
Quantum: de Broglie's Theory of the, and the Doppler Principle, G. E. M. Jauncey, L. de Broglie, 51; Theory of Dispersion, The, Dr. H. A. Kramers, G. Breit, 310
Radial Velocities and the Curvature of Space-time, Dr. L. Silberstein, 347

Radiation, A Biological Study of, H. A. Colwell and Prof. S. Russ, 313
Radium C, The Preparation of Line Sources of, Dr. G. H. Henderson, 503
Rainbows, the Light of, Polarisation of, G. B. Deodhar, 860
Relativity, Optical Records and, Prof. H. Wildon Carr, Prof. C. Lloyd Morgan, 681
Resonance Radiation in Magnetic Fields, Polarisation of, A. Ellett, 931
Rockets and High Altitude Research, Prof. R. H. Goddard, 574
Round Liquid Columns, The Influence of the Degree of Instability on the Phenomena of, R. A. Castleman, Jun., 857
St. George Expedition to the Pacific, The, J. Hornell, 681
Sap in Trees, Flow of, Prof. A. S. Eve, 827
Scandium Lines, The Magnetic Resolution of the, S. Goudsmit and Prof. P. Zeeman, 432
Science : and Labour, Major A. G. Church, 89 ; Exhibitions, Popular, A. S., 683
" Scientist," The Word, or its Substitute, Dr. N. R. Campbell, 788 ; Sir E. Ray Lankester ; Sir Clifford Allbutt, 823 ; H. W. Fowler ; J. H. Fowler ; Prof. D'Arcy W. Thompson ; Prof. W. J. Sedgefield ; Sir Oliver Lodge ; Prof. W. R. Chambers ; Sir Israel Gollancz, 824 ; Prof. H. Wildon Carr, 825 ; Prof. H. Dingle ; Sir R. A. S. Paget, Bart., 897 ; a Chemist, 898
Scorpion Spermateleosis, The, Prof. J. B. Gatenby, 380
Scorpions, Gametogenesis of, Cell Inclusions in the, Vishwa Nath, 52
Scotoscope, The, C. E. Benham, 11
Sea Waves, A New Method of Investigating, Prof. W. Shoulejkin, 498
Senescence, Growth and, Theories of, Prof. T. B. Robertson, 896
Sex in Mushrooms and Toadstools, Experiments on, Prof. A. H. R. Buller, 826
" Shear " in Geometry, The Use of, A. Mallock, 9
" Ship-designs " on Prehistoric Egyptian Vases, The, Dr. H. O. Forbes, 499
Slug, The Large Black, at Honolulu, Prof. T. D. A. Cockerell, 502
Sociology, Biology and, C. W. Soal, 273 ; Dr. B. Malinowski, 274
Sound Records, Analytical, Dr. E. E. Fournier d'Albe, 537
South-west Monsoon, Microseisms associated with the Incidence of the, S. K. Banerji, 576
Space-time, the Curvature of, Radial Velocities and, Dr. L. Silberstein, 347
Spectrohelioscope, The, F. Stanley, 683
Spiders of the Madeira Islands, The, Prof. T. D. A. Cockerell, 11
Starch Content of Plants, Polarised Light and, E. Sidney Semmens, 719
Stark Effect, The, on Fundamental (Bergman) Series, Dr. T. Takamine, 433
Stars, The Pressure in the Reversing Layer of, and Origin of Continuous Radiation from the Sun, Prof. Megh Nad Saha, 155
Stonehenge, Recent Work at, Rev. Prof. A. H. Sayce ; Lt.-Col. W. Hawley, 503
Sulphur : Suspensions, The Colour of, Dr. E. T. Paris, 827 ; Vapour, Absorption Spectrum and Constitution of, Predissociation of Molecules, Dr. V. Henri and M. C. Teves, 894
Surface Tension and Fine Particles, Dr. E. F. Burton, 502
Syndosmya alba and *Cardium fasciatum*, On Early Sexual Maturity in the Molluscs, Dr. J. H. Orton, 244
Tartaric Acid, the Rotatory Dispersion of, W. T. Astbury, 122 ; Prof. T. M. Lowry and Dr. P. C. Austin, 430
Titanium, Ionised, Regularities in the Spectrum of, Nalini Kanta Sur, 611
Uranium : Nitrogen and, Dr. P. D. Foote, 789 ; Thorium and Radium, the Atomic Weights of, Need for the Redetermination of, Dr. A. S. Russell, 717
Vacuum Tube Discharges, Oscillations in, Prof. R. Whiddington, 193
Velella at Port Erin, Sir W. A. Herdman, 124
Verse : The Biology of, Prof. E. W. Scripture, 825 ; The Physical Nature of, Prof. E. W. Scripture, 534 ; Rev. E. W. Lummis, 682
Volcanic Gases, Emission of, Lord Rayleigh ; Dr. A. A. Robb ; Dr. G. P. Bidder ; J. Place, 50
Wave-lengths, Comparison of, with a Fabry and Perot Étalon, H. D. Babcock, 276
Waves, Wind and, A. Mallock, 679
Wind and Waves, A. Mallock, 679
X-ray Absorption Edges, Fine Structure of, Dr. Katherine Chamberlain, 500
X-rays, Specular Reflection of, H. E. Stauss, 88
Zeeman Effect in Strong Magnetic Fields, The, Dr. P. Kapitza and H. W. B. Skinner, 273
von Zeipel's Red Star near M 37, F. H. Seares, 313
Zirconium, The Mass Spectra of, and some other Elements, Dr. F. W. Aston, 273
Zoological Nomenclature : Generic Names for the Official List, Dr. C. W. Stiles, 382 ; Thirty-five Generic Names of Mammals, Dr. C. W. Stiles, 313

Corrosion Research Committee of the Institute of Metals, Seventh Report to the, G. D. Bengough and R. May, 487
Cotton : Absorption of Vapours of Various Liquids by, R. C. Brimley, 432 ; Cloth Factories, The Use of Artificial Humidity in, Appointment of a Committee on, 728 ; Cytology of, H. J. Denham, 909 ; Diseases occurring in the Sudan, Massey and others, 208 ; in Australia, Dr. W. L. Balls, 819 ; The Possibilities and the Limitations of Australia as a Cotton-growing Country, R. Harding, 819 ; Recent Industrial Research in, 369 ; The Chemistry of, P. H. Clifford and M. E. Probert ; and H. J. P. Venn, 516
Coulomb's Law and the Hydrogen Spectrum, E. B. Wilson, 703
Courants alternatifs, Théorie générale sur les, M. E. Piernet. Fasc. I., 241
Courtine, The Experiments at, P. Villard, 667
Cow's Milk with Antirachitic Properties, Production of, Lesné and Vagliano, 595
Cracking, Recent Development in the Art of, Dr. A. E. Dunstan and R. Pilkethley, 629
Crepidula fornicata, English Enemies of the American Slipper-limpet, Dr. J. H. Orton, 312
Cretaceous Fern, A Lower, Prof. A. C. Seward, 695
Crete, Archæological Work in, Sir Arthur Evans, 619
Crinoids : A Monograph of the Existing, Dr. A. H. Clark. Vol. I. : The Comatulids. Part 2, 345 ; Tertiary, Scarcity of, Dr. F. Springer, 172
Cristaux, La structure des, déterminée au moyen des rayons X, Prof. C. Mauguin, 822
Crop : Production, Present-day Problems in, Sir E. John Russell, 250, 434 ; Yield, The Physiology of, Dr. F. F. Blackman and others, 293
Crustacean, A New, T. Monod, 171
Crystal Structure : Analysis of, by X-rays, Sir William H. Bragg, 248 ; Discussion on, Prof. W. L. Bragg, 912
Crystalline : Fibre, Structure of the Living, A. Busacca, 262 ; Structure, The Carbon Atom in, Sir William H. Bragg, 862
Crystals : and Cells, 233 ; Formation of, T. V. Barker ; H. Griffiths, 767 ; Metal, Some Properties of Single, P. W. Bridgman, 920 ; Mobile Components of, Dr. Hüttig, 658 ; of Metallic Bismuth, The Thermal Expansion of, J. K. Roberts, 773 ; of the Calcite Type, A Theoretical Calculation of the Rhombohedral Angle of, Profs. W. L. Bragg and S. Chapman, 737 ; Rock-salt, The Electrical Conductivity of, Dr. D. v. Seelen, 911 ; The Production of Large, by annealing Strained Iron, Prof. Edwards and Mr. Pfeil, 15
Cultural Relations between the Peoples of the British Commonwealth and the Union of Socialist Soviet Republics, Society for, Establishment of a, 132
Current Meter Rating, Dr. P. Phillips, 367
Cyclones : The Cause of, A. H. R. Goldie, 786 ; The Paths of, 657
Cytology and Evolution, Prof. J. Graham Kerr, 949
Cytoplasm and Nucleus, Mass Relations of, Prof. R. W. Hegner, 23

Dairy Farming Projects, Prof. C. E. Ladd, 822
Dalhousie University, Resignation of Prof. Fraser Harris, 324
Damaging Temperatures and Orchard Heating in the Rogue River Valley, Oregon, F. D. Young and C. C. Cate, 370
Datura, Alkaloids from, 482
Daylight, Artificial, Dr. L. C. Martin, 53, 134

DEATHS.

Abercromby of Aboukir and Tullibody (Lord), 583, 617
Bayliss (Sir William), 364, 474
Beard (Dr. J.), 904
Beilby (Sir George), 199, 361
Bertin (L. E.), 724
Bradley (F. H.), 476, 546
Britten (J.), 583
Burke (Miss K. A.), 166, 250
Campbell (Dr. J. E.), 547, 651
Crawley (A. E.), 689
Creighton (Prof. J. E.), 724
Darroch (Prof. A.), 476, 521
De Stefani (Prof. C.), 942
Deville (Dr. E. G.), 618
Deyl (Prof. I.), 57
Dobbie (Sir James J.), 198
Doflein (Prof. F.), 476, 831
Fitzmaurice (Sir Maurice), 760, 794
Geikie (Sir Archibald), 724, 758
Gilpin (Prof. J. E.), 476
Gude (G. K.), 760
Hehner (O.), 547, 582
Hemsley (Dr. W. B.), 583, 616
Herdman (Sir W. A.), 131, 165, 166
Hesse (Prof. A.), 286
Hlava (Prof. I.), 942
Hough (R. B.), 794
Hovey (Dr. E. O.), 618, 690
Huggenberg (Dr. C.), 832
Hunter (Prof. J. I.), 902
Jaumann (Prof. G.), 760
Jude (Dr. R. H.), 286
Kidston (Dr. R.), 96, 321
König (Dr. E.), 794
Kraemer (Prof. H.), 583
Leudesdorf (C.), 251
Little (Dr. G.), 17
Locey (Prof. W. A.), 690
Long of Wraxall (Viscount), 510
Longbottom (Prof. J. G.), 57
Love (Col. H. D.), 724
Ludlow (Dr. Clara S.), 690
Lupton (H.), 440
Lynch (R. I.), 942
Macfadyen (Prof. W. A.), 690
Marshall (Prof. A.), 96
Martin (Dr. S.), 476, 545
Mendenhall (Dr. T. C.), 476
Moeller (Dr. J.), 651
Moulton (Prof. C. W.), 618
Moyse (Dr. C. E.), 57
Mrázek (Prof. A.), 322
Natorp (Prof. P.), 322
Newcombe (Dr. C. F.), 903
Oberthür (C.), 17
Perkins (H. I.), 760
Počta (Prof. F.), 17
Precht (Prof. H.), 166
Pruvot (Prof. G.), 690
Pufahl (Prof. O.), 942
Roth (Dr. S.), 618
Rowett (J. Q.), 547
Russell-Wells (Sir Sydney), 96, 131
Schaeberle (Dr. J. M.), 618
Schrader (Prof. F.), 904
von Seeliger (Prof.), 942
Seth (Prof. J.), 166, 285
Simon (E.), 942
Slovzov (Prof. B. I.), 440
Smith (H. G.), 547
Stevenson (Dr. J. J.), 364
Stewart (Prof. C. H.), 17
Tannhäuser (Prof. F.), 942
Tatham (Dr. J. F. W.), 904
Teall (Sir Jethro), 57, 95
Thomson (R. W. M.), 724
Veitch (Sir Harry), 57, 95
Watson (Prof. T. L.), 904
Wertheimer (Prof. J.), 250
Wheldon (J. A.), 904
Woodward (Dr. R. S.), 199, 510
Worcester (D. C.), 96

De Broglie's Theory of the Quantum and the Doppler Principle, G. E. M. Jauncey ; L. de Broglie, 51
Decimal : Association, Conference organised by the, 96 ; Coinage and the Metric System, The Means of Securing the Adoption of, 549
Deer-stalking in Scotland, A. I. McConnochie, 412
Deflagrations, The Speed of, E. Jouguet, 523
Degenerate Systems, The Quantum Dynamics of, A. M. Mosharrafa, 882
Delaware River Bridge, The, 625
Democracy, Sir Leslie Wilson, 701
Density and Diffusion Measurement by Displacement Interferometry in Extreme Cases, Dr. C. Barus, 703
Desmidiaceæ, British, Prof. F. E. Fritsch, 783
Determinant to Tensor, From, Dr. W. F. Sheppard, 339
Determinants, On Mixed, R. S. Vaidyanathaswamy, 110
Dewar, James, 1842–1923 : A Friday Evening Lecture to the Members of the Royal Institution, on January 18, 1924, Prof. H. E. Armstrong, 48
Dew-point Hygrometer, A New, Dr. M. Holtzmann, 839
Diabetes under Insulin Treatment, Hydremia in the Course of, F. Widal, P. Abrami, A. Weill, and Laudat, 147
Diamond, The Transformation of the, at a High Temperature *in vacuo*, P. Lebeau and M. Picon, 955
Diamonds, The Production of, Duparc and Kovaleff, 553
Diazonium Tetrachloroiodides and Plumbichlorides, Dr. F. D. Chattaway, F. L. Garton, and G. D. Parkes, 838
Dielectric Mineral Separation, Prof. S. J. Truscott, 793
Dientamœba fragilis in a Child, W. H. Taliaferro and E. R. Becker, 136
Differential : Elevation near Sydney, C. Hedley, 300 ; Equations in Applied Chemistry, Profs. F. L. Hitchcock and C. S. Robinson, 84
Diffusion as a Factor in Ore Deposition, M. Watanabé, 367
Dimethylpentanones, Study of Two Symmetrical and Unsymmetrical, A. Haller and R. Cornubert, 371
Dimorphothera pluvialis (L.), Sleeping Reactions of the Inflorescences of, E. Heinricher, 263
Dinosaurian Remains, Find of, in Nyasaland, 547
Dinotherium, Skull of, late Capt. R. W. Palmer, 624
Diphenyl Propane, The Isomeric $\alpha\alpha$ and $\alpha\gamma$ Compounds of 2 : 4 : 6 : 3′ : 4′-pentamethony, J. J. Drumm, N. O'Reilly, and H. Ryan, 954
Diphtheric Anatoxine, The Properties of, G. Ramon, 396
Diptera, Higher, Structure and Metamorphosis in the, R. E. Snodgrass, 766
Direction-finding by Radio, Dr. R. L. Smith-Rose, 948
Dirigible Programme, The British, 842
Discovery, The forthcoming work of the, 869
Disease : Prevention of, Maj.-Gen. Sir David Bruce, 213 ; Resistance, A Biochemical Basis to, Marañon, 657 ; Science, the Church and, 741
Dispersion, The Quantum Theory of, G. Breit ; Dr. H. A. Kramers, 310
Dissociation and Ionisation by Collision, The Statistical Theory, with Applications to the Capture and Loss of Electrons by α-Particles, R. H. Fowler, 75
Diving in Birds, 494
Dominion Astrophysical Observatory, Victoria, B.C., The, 764
Doppler Effect, The, and Canal Rays, Dr. H. Krefft, 658
Double Fourier Series of a Discontinuous Function, The, E. C. Titchmarsh, 74
Dragonflies from the Biological Station at Lunz, Lower Austria, etc., O. Starch, 184
Drawing Instruments, W. H. Harling's Catalogue of, 203

Drift Indicator, A New, J. N. Carruthers, 718
Dublin, Trinity College, conferment of honorary degrees, 29
Duddell Memorial Medal of the Physical Society of London, Prof. C. V. Boys awarded the, 944
Dumontite, a New Radioactive Mineral, A. Schoep, 703
Durham University: opening of the New College of Pure Science by Sir William H. Bragg; an honorary degree conferred on Sir William H. Bragg, 557; Philosophical Society, election of officers and committee, 692
Dust in the Atmosphere, Prof. J. J. Nolan, 720
Dwarfed Males Parasitic on the Females in Oceanic Anglerfishes (*Pediculati Ceratioidea*), C. Tate Regan, 882
Dyes, A New Group of, from Poison Gases through the 2-aminothiazoles as Intermediates, M. T. Bogert and M. Chertcoff, 920
Dyestuff Industry, Research and the, 478
Dyestuffs Corporation, The British, Prof. W. M. Gardner; Dr. Levinstein, 592
Dynamique des solides, Dr. J. Reveille, 45

Early Man in East Anglia, Works of, 878
Earth: Origin and Structure of the, 742; Physical Constitution of the, R. Yamamoto, 172; The, its Origin, History, and Physical Constitution, Dr. H. Jeffreys, 742; Tides and Ocean Tides: Dr. J. W. Evans, 49; and Local Geology, W. D. Lambert, 572; Dr. J. W. Evans, 749; went Dry? If the, Sir Napier Shaw, 684; -worms of the Genus Pheretima, The Blood-glands of, Dr. J. Stephenson, 73
Earthquake: in Birmingham and District, 653; in Inverness-shire, 323
Earthquakes: observed in France during 1923, E. Rothé and Mme. A. Hée, 811; on Predicting, Prof. T. A. Jaggar, 621
Earth's Crust, The, F. W. Clarke and H. S. Washington, 910
East: African Parliamentary Commission, The, and its Possibilities, 323; Anglian Institute of Agriculture, Chelmsford, D. B. J. Wallace appointed principal of the, 71
Eastern Clan, The Home of an: a Study of the Palaungs of the Shan States, Mrs. Leslie Milne, 929
Echinoderms, the Eggs of, The Process of Cell Division in, J. Gray, 810
Eddington's Relativity, 782
Edible Earth from Travancore, D. Hooper, 789
Edinburgh: and East of Scotland College of Agriculture, Classes at the, 665; University: changes in the staff of; Dr. F. Walker awarded a Rockefeller Travelling Fellowship, 106; conferment of doctorates, 143, 144; Dr. D. M. Lyon appointed Christison professor of therapeutics; Lt.-Col. E. D. W. Greig appointed lecturer in tropical diseases; Dr. D. P. D. Wilkie appointed professor of surgery, 144; remuneration of the staff of, Prof. Barger, 652; new Chemistry Department, opening of, by the Prince of Wales, 875; conferment of an honorary degree upon the Prince of Wales, 875; changes of Deans; Dr. C. B. Ker appointed a senior lecturer, 915; gift by Dr. A. H. Freeland Barbour; scheme for the extension of the Department of Surgery, 952
Education: How to Experiment in, Prof. W. A. McCall, 423; in Schools, The Purpose of, the President of the Carnegie Foundation for the Advancement of Teaching, 334; Views on, Dr. R. Steiner, 450; Week in America, An, 370
Educational Harmonics, 167
Eggs: Double, Prof. T. H. Morgan, 136; from Infected and Immunised Hens, H. G. May, 515
Egypt: Ancient, Racial Intrusions in, Sir Flinders Petrie, 171; Immigrant Cultures in, Sir Flinders Petrie, 16; Prehistoric Ivory Figurine from, Sir Flinders Petrie, 587; The Mother Goddess in, J. Lewis, 22
Egyptian: Affinities in Indian Funerary Practices, Dr. G. S. Ghurye, 515; Government Almanac for 1924, The, 21; Vases, Prehistoric, The "Ship-designs" on, Sir Flinders Petrie, 645
Einstein Theory, The, and a Possible Alternative, Prof. W. P. Montague, 318
Einstein's Theory: of Gravitation, The Foundations of, E. Freundlich. Translated by H. L. Brose. Second edition, 820; of Relativity, Substance and Function and, Prof. E. Cassirer. Translated by Drs. W. C. and M. C. Swabey, 187
Eisenhüttenkunde: Lehrbuch der, verfasst für den Unterricht, den Betrieb und das Entwerfen von Eisenhüttenanlagen, Prof. B. Osann. Zweite Auflage. Erster Band, 235
Electric: Arc with Non-incandescent Cathodes, The, Dr. A. Günther-Schulze, 873; Arcs with Non-Incandescent Cathodes, Dr. H. Stolt, 553; Charges by Friction, H. E. Goodson, 159; Current considered as a Circulation of Equal Charges of Opposite Signs, The, F. Guéry, 955; Discharge, A Rotational "Fatigue" Effect of the, J. Taylor, 382; Fields, Strong, such as those of Thunderclouds, The Acceleration of β-particles in, C. T. R. Wilson, 918; Motors and Control, Principles of, G. Fox, 346; Power, Coal and, 417; Sparks, P. O. Pedersen, 148; Substations, Small Automatic, Rogers, 795; Waves: at the Surface of Separation of Two Solids, A. Stoneley, 773; Short, A New Source of, Mrs. A. A. Glagolewa-Arkadiewa, 65
Electrical: Conductivity and Bohr's Theory of Atomic Structure, O. Feussner, 447; Design, Elements of, Prof. A. Still, 571; Engineering, A Hundred Years of, Prof. G. W. O. Howe, 229, 277; Engineers, Institution of: Conversazione of the, 18; Sir Oliver Lodge elected an honorary member of the, 727; Generators, the Brushes of, Measurement of the Heating of, H. Robert, P. Vernotte, and A. Jeufroy, 594; Industry, The Growth and Outlook of the, W. B. Woodhouse, 691; Instruments, 304; Measuring Instruments. Part I.: Commercial and Indicating Instruments, Dr. C. V. Drysdale and A. C. Jolley, 304; Method of producing Vowel Sounds, An, and its Application to Wireless Telegraphy, Prof. W. H. Eccles and C. F. A. Wagstaffe, 844; Precipitation, Sir Oliver Lodge, 664; Progress and its Unsolved Problems (James Forrest Lecture), Prof. Elihu Thomson, 105; Terms: A Dictionary of, for Electrical Engineers and Students, S. R. Roget, 497; Time-marking System, A Simple, for Use with Self-recording Meteorological Instruments, L. H. G. Dines, 109; Vibration Instruments: an Elementary Text-book on the Behaviour and Tests of Telephone Receivers, Oscillographs, and Vibration Galvanometers, Prof. A. E. Kennelly, 304
Electrically Fused Refractory Materials, A Centrifugal Method of making Small Pots of, F. S. Tritton, 881
Electricity: and Magnetism for Advanced Students, S. G. Starling. New edition, 927; Contact, A. Coehn and A. Cuss, 947; for Auxiliary Power on Ships, G. Austin, 801
Electrification: due to Bubbling Gases through Fluid Metals, A. Coehn and E. Duhme, 658; of Two Parallel Circular Discs, Prof. J. W. Nicholson, 72
Electrodeless Discharge, The, Dr. P. D. Foote and A. E. Ruark, 750
Electrode Reaction and Equilibria: a General Discussion held by the Faraday Society, Nov. 1923, 714
Electro-Endosmosis, F. Fairbrother and H. Mastin, 911
Electrolytic Rectifier, The, for Electrical Engineers, Physicists, and Wireless Amateurs, N. A. de Bruyre, 462
Electronic Battery, An, J. B. Kramer, 873
Electrons: in Optically Excited Mercury Atoms, Controlled Orbital Transfers of, Prof. R. W. Wood, 738; The Emission of, caused by α-Rays, Dr. A. Becker, 588; which scatter γ-Rays, The Recoil of the, D. Skobelzyn, 838
Electroplating and Electroforming (Electrotyping), Principles of, W. Blum and G. B. Hogaboom, 272
Elements: Geochemical Distribution of the, Prof. V. M. Goldschmidt, 445; Transformations of, Prof. A. Smits, 609
Elephant in America, Pre-Columbian Representations of the, Dr. H. O. Forbes, 174
Elephants: and Ethnologists, Prof. G. Elliot Smith, 923; "in American Art," 923

Elliot Medal of the National Academy of Sciences, Washington, The, 833
Empire: Cotton Growing Corporation, Report of the, 761; The Resources of the, Series, Vol. I. Part I.: Crops and Fruits, Prof. J. R. Ainsworth-Davis; Vol. I. Part II.: Meat, Fish, and Dairy Produce, Prof. J. R. Ainsworth-Davis; Vol. II.: Timber and Timber Products, including Paper-making Materials, edited by S. J. Duly; Vol. III.: Textile Fibres and Yarns, J. S. M. Ward; Vol. V.: Rubber, Tea, and Cacao; with Special Sections on Coffee, Spices, and Tobacco, compiled and edited by W. A. Maclaren; Vol. VI.: Leather, Hides, Skins, and Tanning Materials, Dr. E. C. Snow, 526
Emulsions, Reversible, Viscosity of, S. S. Joshi, 882
Encke's Comet, 203, 366, 444; L. Matkiewicz, 62
Engine Balance, A Treatise on, using Exponentials, P. Cormac, 674
Engineering: and Shipbuilding, J. H. Hume; T. Westgarth, 664; Formulas, The Design of Diagrams for, and the Theory of Nomography, Dr. L. I. Hewes and H. L. Seward, 674; History, Studies in, 925; Non-Ferrous Metals and Alloys, Dr. L. Aitchison and W. R. Barclay, 427
Engineers, Junior Institution of, Dr. A. Russell elected president of the, 906
Entomological Meeting at Pusa, The Fifth, 201
Entomology, Medical and Veterinary, a Textbook for Use in Schools and Colleges as well as a Handbook for the Use of Physicians, Veterinarians and Public Health Officials, Prof. W. B. Herms. New edition, 426
Entomostraca: collected in the vicinity of Auckland, N.Z., Marguerite Henry, 452; Diagnoses of New, Part III., V. Brehm, 263; from Colorado, G. S. Dodds, 63; from Dried Mud, Breeding, and their Habits in Aquaria, Marguerite Henry, 452
Eobuthus Fritsch, Morphology of, L. J. Wills, 953
Eolithic Ornament and Art, J. Reid Moir, 861
Epacridaceæ, Studies in the, I., P. Brough, 212
Equation of Lagrange studied by Cayley, An, N. Nielson, 148
Esquimalt, B.C., new dry dock at, 585
Estuary Tides, Computation of, Dr. B. Dawson, 64
Ether, The Carrying Away of the, and the Aberration of Stars, E. Brylinski, 955
Ethereal Radiations, Atoms and, Dr. R. A. Millikan, 141
Ethers, the Preparation of, General Method for, J. B. Senderens, 955
Ethylene: Oxides, The Isomerisation of the, with Migration, Tiffeneau, A. Orékhoff, and Mlle. J. Levy, 845; The Catalytic Activation of, by Organo-metallic Nickel, A. Job and R. Reich, 371
Eucalypts of the Blue Mountains and their Defined Areas, E. C. Chisholm, 300
Eucalyptus: A New Species of, from Southern N.S.W., W. A. W. de Beuzeville and M. B. Welch, 919; *piperita* and its Essential Oils, Notes on, Part I., A. R. Penfold and F. R. Morrison, 336; Woods, The Structure of Some, M. B. Welch, 919
Eugenics: A Bibliography of, Prof. S. J. Holmes, 271; International Commission of, meeting of, in Milan, 513
Europe: Periodicity of Temperatures in, A. Wagner, 911; The Continent of, Prof. L. W. Lyde. New edition, 927
European Upper-air Data, Further Researches into the, C. K. M. Douglas, 109
Europeans: in the Indian Services, 41; in Tropical Countries, The Clothing of, Prof. P. F. Fyson, 869
Evaporation, The Kinetic Theory of, D. B. Macleod, 883
Everest, Mount, Expedition: the death of G. L. Mallory and A. C. Irvine, 60; Memorial Service for Mallory and Irvine, 618; N. E. Odell, 943
Evergreens, The Cultivated: a Handbook of the Coniferous and most important Broad-leaved Evergreens planted for Ornament in the United States and Canada, edited by Prof. L. H. Bailey, 240
"Evolution: at the Crossways," H. Reinheimer, 496, 611; G. P. B., 611; Cytology and, Prof. J. Graham Kerr, 949; Geology and, Prof. W. W. Watts, 539; Knowledge and Revelation: being the Hulsean Lectures delivered before the University of Cambridge, 1923–1924, Rev. S. A. McDowall, 606; Mendelism and, J. T. Cunningham, 9, 537; C. Dover, 10; J. S. Huxley, 464
Examiners, Psychologists and, 489
Exhibition of Pure Science, Handbook to the [British Empire Exhibition], arranged by the Royal Society, 462
Exhibitions, Popular Science, 633
Explosions: and Zones of Silence, L. Gazaud, 326; Study of, Sir Oliver Lodge, 10; P. J. Ryle, Dr. H. Jeffreys, 123
Explosive: Fruit, An, 657; Waves, The Propagation of, T. Vautier, 335
Eye, the Living, The Microscopy of, Dr. H. Butler, 179

Falt-products, Calculation with, in its Application to Figures of the Second Degree in Space, E. Müller, 300
Faraday: House Electrical Engineering College, Dr. W. R. C. Adams appointed assistant lecturer and demonstrator to, 952; -Maxwelliennes, Nouvelles Vues, C. L.-R.-E. Mengès, 85; Society, Prof. F. G. Donnan elected president; Annual Report of the, 134
Farming, Practical, 817
Fats, Dr. E. F. Armstrong and J. Allan, 133
Fatty Materials, The Acetyl Index of, E. Raymond and G. Clot, 111
Fauna of British India, including Ceylon and Burma. Edited by Sir Arthur Shipley. Birds: Vol. II. E. C. Stuart Baker. New edition, 427
Faune de France. 7: Pycnogonides, Prof. E.-L. Bouvier, 272
Federalisation of American Graduates, 298
Fenchol, The Origin of, in the Reaction of Bouchardot and Lafont, M. Delépine, 111
Fermentation: Industries, The, R. Furness, 491; The Chemist and the, J. L. Baker, 735; Influence of Certain Colloids upon, Part I., R. Greig-Smith, 956
Ferric Chloride and Potassium Thiocyanate, The Reaction between, K. C. Bailey, 775
Ferrous: Alloys Research, The Iron-oxygen Equilibrium, Dr. W. Rosenhain and others, 554; Oxide, The Decomposition of, G. Chaudron and H. Forestier, 147
Fertility and Sterility in Domestic Animals, J. Hammond, 252
Field: Crops: The Production of, a Textbook of Agronomy, Profs. T. B. Hutcheson and T. K. Wolfe, 817; Museum of Natural History, Lectures for Children at the, 832
Fight against Disease, The, October, 762
Fijian Butterflies, Mimicry among, Prof. E. B. Poulton, 809
Films, Thin: Electrical Properties of, Dr. A. Frumkin, 158; The Molecular Structure of, Pt. VI., N. K. Adam and J. W. W. Dyer, 772
Finsbury Technical College, The Impending Closing of the, 735
Fireball: Large, 135; The Great, of Nov. 11, W. F. Denning, 836
Fireballs, W. F. Denning; E. G. Fenton, 764
Fireclay Corrosion through the Action of Saltcake, Prof. W. E. S. Turner, 955
Fishery: Problems, Good Government and, Mr. Hoover, 168; Superintendents, The appointment of, D. G. Stead, 512
Fishes: Primitive, and Petroleum, 671; The Evolution and Distribution of, Prof. J. M. Macfarlane, 671; the Source of Petroleum, Prof. J. M. Macfarlane, 671
Five- (and Six-) Point Support: "Right as a Trivet," Sir G. Greenhill, 463; Dr. J. W. French, 575
Flax Seed and Flax in the British Isles, the Growing of, Appointment of a Committee on, 620
Flight, Mechanical, The Coming of Age of, 867
Flint Implement Working-site in the Medway Valley, W. A. Cook, 879
Flowering and Growth, Effect of Length of Day on, M. A. H. Tincker, 350
Flowers, Insects and, Dr. E. J. Salisbury, 92
Fluorine and Hydrogen Fluoride, J. Simons, 801

Fluxes and Slags in Metal Melting and Working : a General Discussion held by the Faraday Society and the Institute of Metals, with the Co-operation of the British Non-Ferrous Metals Research Association and the Institute of British Foundrymen, April 1924, 892
Fly and Bait Casting, The Principles and Practice of, R. D. Hughes, 497
Fog, A Bad, 906
Food : Chemistry in Relation to, Dr. G. W. Monier-Williams, 491 ; Investigation Board, The Function of the, W. B. Hardy, 257 ; Preservatives : Committee, Interim Report of the, 448 ; and their Action, 448 ; in, Report of Departmental Committee on, 877
Foot-and-mouth Disease : Relation of Wild Birds to the, W. P. Taylor and H. C. Bryant, 547 ; The Origin of, C. D. Perrine, 60 ; The Virus of, Profs. Frosch and Dahmen, 18
Foraminifera, Miocene, Heron-Allen and Earland, 482
Forest Soils, Composition of, A. Němec and K. Kvapil, 595
Forestry Commissioners, Fourth Annual Report of the, 168
Forrest, James, Lecture, Prof. Elihu Thomson, 105
Fossil Plants of the Calamopitys Type, from the Carboniferous Rocks of Scotland, Dr. D. H. Scott, 146
Fossils in the National Museum, New or Little-known, Pt. XXVIII., F. Chapman, 523
Foundations, Abutments, and Footings, 7
Foundry Work, Education in Relation to, 334
Franklin Institute : The, 726 ; award of medals to Dr. H. Fletcher, T. C. McBride, and M. R. Sheen, 763 ; Centenary of the, 386 ; medals, presentation of, to Sir Ernest Rutherford and Dr. E. Weston, 621
Free : -air Temperatures and Wind Directions, W. R. Gregg, 23 ; Atmosphere in India, The, J. H. Field and Dr. W. A. Harwood ; W. H. Dines, 448 ; Trade Doctrine, A Retrospect of, Sir William Ashley, 229
Freezing-points of Solutions containing Ferric Chloride and Potassium Thiocyanate, K. C. Bailey and J. D. Kidd, 775
Freiburg-im-Breisgau University, Dr. W. Eitel invited to the chair of mineralogy in, 915
French Textile Machinists, Work of, 254
Frequency Curves : and their Application in the Analysis of Death Curves and Life Tables, An Elementary Treatise on, A. Fisher. Translated from the Danish by E. A. Vigfusson. American edition, 345 ; of Genera and Species, G. U. Yule ; Dr. W. L. Balls, 10
Friction for Metallic Surfaces, Coefficient of, M. Fichter, 173
Frog, the Pituitary of the, Certain Abnormalities occurring in, H. R. Hewer, 809
" Fundamental Research, On the Encouragement of," 762
Fungi : and Epileptiform Convulsions, Prof. J. R. Greig, 837 ; and Plant Diseases : Outlines of, for Students and Practitioners of Agriculture and Horticulture, F. T. Bennett, 306 ; Variability in, H. R. Britton-Jones, 482
Fungicides, The Co-ordination of Investigations of, F. Tattersfield and others, 207

Galapagos : Archipelago, The, Prof. J. Stanley Gardiner, 411 ; World's End, W. Beebe, 411
Galvanometer, A New Loop, 662
Gas : Bubbles in Water, The Cataphoresis of, T. Alty, 772 ; Engineers' Compendium : a Collection of Statistics, Formulæ, Rules and Data for the Everyday Use of Gasworks Officials and Students. Compiled by Experts, 461
Gaseous : Ionisation, Chemical Studies in, Pts. I. and II., R. W. Lunt, 72 ; Systems, A Thermal Method for the Study of, G. Piccardi, 262
Gases : at Various Pressures, The Temperature Gradient in, W. Mandell and J. West, 773 ; Critical Potentials of, The Measurement of, E. G. Dymond, 75, 882 ; The Specific Heats of, Prof. J. R. Partington and W. G. Shilling, 927
Geiger α- and β-particle Counter, The, Dr. H. Geiger, 625
Geikie, Sir Archibald, Sir A. Strahan, 114
Gelatin : The Influence of, on the Stability of a Colloidal Solution of Cholesterol and on the Charge on the Particles, P. MacCallum and W. V. Kermak, 954 ; The Shrinkage of, Prof. D'Arcy W. Thompson, 576 ; E. Hatschek, 643
Genetics : and Practical Breeding, Major E. N. Wentworth, 206 ; The Relation of Plant Pathology to, F. T. Brooks and others, 293
Gentiacauline, The Fermentation Hydrolysis of, M. Bridel, 739
Geodesy and Geophysics, The International Union of, Meeting at Madrid ; Prof. O. de Buén elected president of the Section of Oceanography, 697
Geographical Aspects, Some, of the British Empire Exhibition, 128
Geography, Economic, Prof. R. H. Whitbeck and Prof. V. C. Finch, 606
Geological : Society Club, centenary dinner of the, 725 ; Survey of Great Britain, Progress in the, 949
Geologists' Association, the Foulerton award of the, to be presented to A. L. Leach, 944
Geology : A Text-Book of, for Use in Universities, Colleges, Schools of Science, etc., and for the General Reader, Profs. L. V. Pirsson and C. Schuchert. Part 2 : Historical Geology, Prof. C. Schuchert. New edition, 376 ; and Evolution, Prof. W. W. Watts, 539 ; in the Service of Man, Prof. W. W. Watts, 228 ; of the Country around Flint, Hawarden, and Caergwrle, C. B. Wedd, W. B. R. King, and others, 950 ; of the Country near Brighton and Worthing, H. J. O. White, 950 ; of the United States, Dr. A. Holmes, 376
Geometry : Plane and Solid, Prof. W. B. Ford and C. Ammerman. Edited by E. R. Hedrick. New edition, 533 ; Principles of, Prof. H. F. Baker. Vol. 3, 83 ; School, A Shorter, H. S. Hall and F. H. Stevens. Part I., 241 ; Three-Dimensional, 83
Geopsychischen Erscheinungen : Die, Wetter und Klima, Boden und Landschaft in ihrem Einfluss auf das Seelenleben, Prof. W. Hellpach. Dritte Auflage, 44
Geothermic Gradient, The, Dr. H. Arctowski, 872
German : Men of Science and Physicians, The Society of, 290 ; Scientific and Medical Association Meeting at Innsbruck, The, 734
Germanium and its Derivatives, Prof. G. T. Morgan and Dr. H. D. K. Drew, 194
Germans from International Congresses, the exclusion of, Prof. G. H. Hardy, 869
Germany and International Congresses, 253
Germination of Seeds exposed to Low Temperatures, H. F. Roberts, 393
Geschichte des Fixsternhimmels, The Preparation of the, Prof. R. Schorr, 203
Geum urbanum × *rivale*, The Supposed Constancy of the Hybrid between the Common and the Water Avens, Prof. F. E. Weiss and D. Rosén, 500
Gewitter, Die Elektrizität der, Dr. K. Kähler, 890
" Gifted Pupil," The, in the High Schools of Iowa, Prof. C. Deich and E. E. Jones, 521
Glaciers of the Mont Blanc Massif, The Waters of the, d'Arsonval, Bordas and Touplain, 522
Glands that regulate Sex, The, Dr. F. A. E. Crew, 779
Glandular Cell : Constitution of the Cytoplasm of a, M. Parat and J. Painlevé, 595 ; in Activity, Vital Observation of a, M. Parat and J. Painlevé, 667
Glasgow University : H. J. W. Hetherington appointed professor of moral philosophy, 144 ; the appointment of Prof. H. H. Dixon approved by the King, 557 ; Prof. H. H. Dixon unable to accept the professorship of botany, 736 ; Hunterian Collections of, Report on the, 1922–23, 654 ; gifts to, 771
Glass : Colourless, Production of, in Tank Furnaces, with special reference to the Use of Selenium, Part IV., A. Cousen and Prof. W. E. S. Turner, 955 ; -houses of the Leeds District in the Seventeenth, Eighteenth, and Early Nineteenth Centuries, F. Buckley, 955 ; Industry in North America, The Present Position of the, Prof. W. E. S. Turner, 738 ; Making, British, 100 Years of, 1824–1924, Chance Bros. and Co., Ltd., 168 ; Technology, S. English and Prof. W. E. S. Turner, 483 ; The Annealing and Re-annealing of, W. M. Hampton, 631 ; The Photo-elastic Constants of, as affected by High Temperatures and by Lapse of Time, F. C. Harris, 881 ; The Viscosity of, H. Le Chatelier, 594, 731
Glassware, Scientific, Standardisation of, 485

Gliding : Birds, The Wings of, Sir Gilbert T. Walker, 182 ; Indian Boomerangs, 183 ; Flight Record, A, Lieut. Thoret, 366
Globular : Clusters and Stars of High Velocity, A Possible Relation between, J. H. Oort, 264 ; Lightning and the Cause of Thunder, E. Mathias, 517
Glycerine, Purifying, from Volatile Fatty Acids and their Esters, A. Kailan and R. Obogi, 263
Glycogen, The Molecular Weight of, Dr. W. Fearon, 752
Glycymeris in Southern Australia, A Revision of the Kainozoic Species of, F. Chapman and F. A. Singleton, 212
Godthaab, Voyage of the, 169
Gold, The Reported Transmutation of Mercury into, 197 ; Prof. F. Soddy, 244
Golden Bough, Leaves from the, Culled by Lady Frazer, 854
Golgi, Holmgren Trophosponge and Vacuome, The Internal Reticular Apparatus of, M. Parat and J. Painlevé, 775
Gonad and Soma in the Fowl, Pézard, Sand, and Caridroit, 656
Government publications, plea for the placing of, in selected public libraries, 547
Graphite : The Crystalline Structure of, O. Hassel and H. Mark, 483 ; The Melting Point of, 173 ; The Structure of, J. D. Bernal, 738
Grassland Farming, Pastures and Leys, W. J. Malden, 817
Graubünden, Switzerland, Album of Views in, 202
Gravimetric Comparison of Rome with Bologna and Padua, G. Cassinis, 631
Gravity : Measurements in Deep Water, Prof. J. Joly, 538 ; Observations on the Indian Ocean and the Results of their Isostatic Reduction, W. Bowie, 930
γ-rays : Extra High Frequency, from Radium, J. Thibaud, 102 : The Absorption and Scattering of, E. A. Owen, N. Fleming, and Miss W. E. Fage, 108
Great Barrier Reef Area, Survey of the, 289, 445
Grey Seals, The Protection of, 832
Grimaldi Man, Neanderthal Man and : their Rôle in the Evolution of Man, Prof. R. Verneau, 899
Grime's Graves, The Protection of, G. Maynard, 878 ; A. L. Armstrong, 879
Growth, G. R. de Beer, 709 ; and Senescence : The Chemical Basis of, Prof. T. B. Robertson, 267 ; Theories of, 267 ; Prof. T. B. Robertson, 896 ; -ratios, Constant Differential, and their Significance, J. S. Huxley, 895
Guinea-pig, The Sensibilisation of the, to C-avitaminosis, G. Mouriquand, P. Michel, and M. Berheim, 595
Gupta Dynasty in Eastern India, Currency of the, N. H. Bhattasali, 587
Gypsy Burial Customs, English, T. W. Thompson, 481
Gyroscope, A Recording, G. F. C. Searle, 76

Haboobs, Notes on, L. J. Sutton, 666
Haddock Biology, Problems in, with special reference to the Validity and Utilisation of the Scale Theory. I. : Preliminary Report, H. Thompson, 333
Hæmoglobin, The Ionic Nature of, H. Taylor, 73
Hair Tracts of Mammals, The, Prof. F. Wood Jones, 946
Haiti, Tertiary Cirripedia from, Dr. H. A. Pilsbry, 64
Hall's Effect in Bismuth in the Case of Weak Fields, E. Adinolfi, 595
Hampshire Gate, The, H. G. Dent, 154
Hawksley, Thomas, Lecture, The, Eng. Vice-Adml. Sir George G. Goodwin, 792
Health and Physique through the Centuries, Dr. F. C. Shrubsall, 230, 646
Hearing : The Theory of, Sir R. A. S. Paget ; G. Wilkinson, 87 ; Prof. E. W. Scripture, 194 ; Dr. H. Hartridge, 243 ; The Resonance Theory of, J. Keen, 572 ; G. Wilkinson, 719
Heat : and a Vacuum, The Action of, on Artificial Graphite, P. Lebeau and M. Picon, 335 ; Insulators, Dr. E. Griffiths, 838 ; The Conduction of, down the Necks of Metal Vacuum Vessels containing Liquid Oxygen, G. R. D. Hogg, 182
Heavens are Telling, The, Prof. E. B. Frost, 691
Hélicoptères : Les, Recherches expérimentales sur le fonctionnement le plus général des hélices : Études sur le mécanique de l'hélicoptère, W. Margoulis, 566
Helium, Mercury and, J. J. Manley, 861
Helix aspera in Australia, T. Steel, 300
Helleborus niger and *H. viridis*, T. E. Wallis and Miss Alison M. Saunders, 695
Helmholtz's Treatise on Physiological Optics. Translated by Prof. J. P. C. Southall. Vol. I., 887
Heredity, An Introduction to the Study of, Prof. E. W. MacBride, 570
Herring Scales, Growth-rings of, H. J. Buchanan-Wollaston, 348
Herschel, Sir William, Eyepieces used by, Dr. W. H. Steavenson, 21
Hertzian : Resonator, The Damping of the Oscillations of a, W. P. Allis, 702 ; Waves, Rôle of the Atmosphere in the Propagation of, J. Guinchant, 371
Heterochromatic Photometry, Prof. Fabry, 329
Hexadecane, The Pyrogenic Dissociation of, H. Gault and F. A. Hessel, 299
Hexahydroaromatic and Saturated Fatty Hydrocarbons, The Catalytic Decomposition of, V. Grignard and R. Stratford, 147
Hexametaphosphates, The Definition and Preparation of the, P. Pascal, 845
High : Frequency Spectra, 237 ; Velocity β-rays, The Production of, by the Action of Hard β-rays, J. Thibaud, 368
Himalaya : The Appeal of the, 673 ; Wonders of the, Sir Francis Younghusband, 673
Historical Tradition and Oriental Research, Dr. J. H. Breasted, 559, 755
Hokkaido Imperial University, The, 701
"Hole, Slot and Plane" Geometrical Constraint, The, W. N. Bond, 502
Holy Ways and Holy Places, Prof. H. J. Fleure, 799
Hongkong, Weather at, T. F. Claxton, 291
Hooke Microscope, The Development of the, Dr. R. S. Clay and T. H. Court, 702
Hop : the Antiseptic Properties of the, Influence of the Reaction of the Medium on, A. Fernbach and I. Stoleru, 336 ; Wild, A Mildew Disease of the, E. S. Salmon and W. M. Ware, 695
Horticultural Research, 332
Howard Prize, The, of the Royal Meteorological Society, awarded to Cadet J. M. Goode, 201
Human : Embryo, Early Development of the, Prof. T. H. Bryce, 729 ; Migrations, Dr. R. le Conte, 946 ; Nutrition, Problems of, 332 ; Ovum, Transplantation of the, Prof. J. H. Teacher, 367 ; Understanding, An Essay concerning, John Locke. Abridged and edited by Prof. A. S. Pringle-Pattison, 462
Huxley Medal of the Royal Anthropological Institute, The, presented to Dr. R. Verneau, 870
Hyades, Proper Motions of the, Prof. van Rhijn, 290
Hydrobromic Acid, Action of, on Some Tertiary Alcohols, Mme. Pauline Ramart, 667
Hydrocarbons, True Acetylenic, A General Method for the Preparation of, M. Bourguel, 702
Hydrodynamics, Dr. H. Lamb. New edition, 638
Hydrogen : and Arsenic, Solid Compounds of, L. Moser and A. Brukl, 183 ; and Oxygen, The Combination of, in the Presence of Activated Mercury, R. G. Dickinson, 847 ; Electron Discharges in, The Striking and Breaking Potentials for, Prof. O. W. Richardson and T. Tanaka, 737 ; -ion Concentration : Colorimetrically in Small Quantities of Fluids, Determining the, R. Greig-Smith, 956 ; of the Soil, The Filtration and Other Errors in the Determination of the, Dr. W. R. G. Atkins, 110 ; Solubility of Phosphates in Relation to, Dr. W. R. G. Atkins, 275 ; Ions in, Different Types of, Dr. H. D. Smyth, 124 ; Peroxide, Relation between the Time of Action and the Concentration of a Sterilising Substance, C. Richet and Mme. A. Le Ber, 111 ; Spectrum of, a *P*, *Q*, and *R* Combination in the Many-lined, Prof. O. W. Richardson and T. Tanaka, 737 ; The Ionisation Potentials of, as interpreted by Positive Ray Analysis, T. R. Hogness and E. G. Lunn, 847
Hygiene in Animal Food : Evidence from Zoological Gardens, Dr. P. Chalmers Mitchell, 653
Hyvac Oil Pump, The, 948

Icebergs in North Atlantic, Prof. R. de C. Ward, 136
Igneous Geology of the Burntisland District, The, D. A. Allan, 110
Illuminating Engineering Developments, L. Gaster, 288, 797
Illumination, J. W. T. Walsh and others, 59; of Objects rotating or vibrating at very High Speeds, The Synchronous and Instantaneous, G. E. Bairsto, 108; The International Commission on, 329; Dr. E. P. Hyde re-elected president, 330
Immunity, Dr. R. A. O'Brien and others, 178; Acquired, The Heredity of, S. Metalnikov, 559; of Birds towards Human Tuberculosis, The Probable Cause of the Natural, etc., J. Auclair, 211
Imperial: Botanical Conference, F. T. Brooks, 293; Cancer Research Fund, Annual Meeting of the, 167; College of Science and Technology: awards at the, 107; award of Dominion scholarships for research work in science, 181; Sir Gilbert T. Walker appointed professor of meteorology, 180; Prof. S. Chapman to be chief professor of mathematics, 29; The Aeronautics Department of the, 451; College of Tropical Agriculture, Gift to the, by the Royal Horticultural Society, 665; Forestry Institute at Oxford, The, 907; Institute Bill, The, 1; Mycological Conference, The, 207
Inbreeding, Effects of, Prof. L. J. Cole, 206
Income Tax of Professional Men, The Assessment for, 251
India: a Bird's-Eye View, Earl of Ronaldshay, 406; A Technological Cotton Research Laboratory in, 870; and its Problems, 406; Early Christian Legends in, Father Hosten, 515; 658; Engineering Education in, 107; Floods in, 585; Forecast of the Monsoon Rainfall in, for 1924, Sir Gilbert T. Walker, 98; Important Archæological Discoveries in, Sir John Marshall, 584, 905; Gadd and S. Smith, 585; Meteorological Department of the Government of, Report of the, 1923–24, Sir Gilbert T. Walker, 389; The Free Atmosphere in, J. H. Field and Dr. W. A. Harwood; W. H. Dines, 448
Indian: Agriculture, Biochemistry in, G. J. Fowler and Y. N. Kotwal; G. J. Fowler and F. Marsden, 326; Crania from South America, Dr. H. ten Kate, 872; Education in 1922–23, 486; Funerary Practices, Egyptian Affinities in, Dr. G. S. Ghurye, 515; Glow-worm, The Life-history of the, Dr. J. C. Hutson and G. D. Austin, 515; Institute of Science, The, Dr. M. W. Travers, 156; Prof. J. F. Thorpe, 157; Prof. S. S. Bhatnagar, 538; Inter-University Board, An, to be constituted, 29; Ocean, Climatology of the, Dr. P. H. Gallé, 731; Philosophy, Prof. S. Radhakrishnan, Vol. I., 714; Services, Europeans in the, 41; Timbers, Research on, 696; Universities Conference, The, P. J. Hartog, 334; Wheat Production, Statistics of, H. K. Trevaskis, 64
Indians, White, in Panama, R. O. Marsh, 59
Indium and Gallium, The Spark Spectra of, in the Extreme Ultra-violet Region, M. Weinberg, 881
Inductance and Capacity, The Calculation and Measurement of, W. H. Nottage. New edition, 605
Induction Motors, The Control of the Speed and Power Factor of, Dr. M. Walker, 190
Industrial: Fatigue Research Board, Report, 27, 254; Hygiene, Some Applications of Physiology to, Prof. E. H. Cluver, 802; Research Associations, The Development of, Dr. Kenneth Lee, 813
Inert Gases on the Earth, The Rarity of the, Dr. F. W. Aston, 786
Infection and Resistance, Prof. H. Zinsser. New edition, 677
Infections, Obscure, The Knowledge of, C. Nicolle, 396
Inflorescence, A Giant, P. Dakkus, 799
Influence Electrostatic Generator, Quantitative Theory of the, A. W. Simon, 559
Infra-red Adsorption Spectra of Organic Substances, Quantitative Studies on the, J. Lecomte, 111
Inquiry by Sample, An: an Experiment and its Results, J. Hilton, 109
Insect: Control, The Principles of, R. A. Wardle and P. Buckle, 7; Fauna of an Indian Island, The, C. Dover, 351
Insectan Palæontology, Dr. R. J. Tillyard, 446
Insects: and Flowers, Dr. E. J. Salisbury, 92; Heads of, Transplantation of, J. T. Cunningham, 124; Dr. W. T. Calman, 467
Instinct and Culture in Human and Animal Societies, Dr. B. Malinowski, 79
Insulin, Prof. H. MacLean, 18, 33; Chemistry of, F. H. Carr, 256; Effect of, on the Lactic Fermentation, A. A. Noyes and H. W. Estill, 920; from the Cod-fish, Dr. H. W. Dudley, 291; -like Substances and their Action on the Exchange of the Carbo-hydrates, M. Eisler and L. Portheim, 263; Studies on, II., Action of Insulin on Zymase, U. Sammartino, 667
Intelligence: Measurement: a Psychological and Statistical Study based upon the Block-design Tests, Prof. S. C. Kohs, 423; The Nature of, Prof. L. L. Thurstone, 819
International: Health Board, Rockefeller Foundation, Report for 1923, 654; Mathematical Congress at Toronto, Prof. J. C. Fields elected president, 590; Meteorological Conference of Directors and of the Committee at Utrecht, The, 289
Interpolation, The Series of, N. E. Nørlund, 147
Inter-racial Problems and White Colonisation in the Tropics, Prof. J. W. Gregory, 228
Iodides, Organic, The Photolysis of the, A. Job and G. Emschwiller, 211
Iodine: Blue Adsorption Compounds of, Prof. G. Barger and F. J. Eaton, 948; in Venous Blood, Presence of, from the Thyroid, E. Gley and J. Cheymol, 811; Vapour, The Ionisation of, by Ultra-violet Light, W. West and E. B. Ludlam, 954
Ionic Mobilities in Gaseous Mixtures, L. B. Loeb and M. F. Ashley, 703
Ionisation: by Positive Ions, Dr. J. Franck, 517; in Solutions, Prof. A. A. Noyes, 64; Potential of an Element, A Law connecting the, with its Boiling Point, N. Perrakis and P. Bedos, 739
Ionised: Nitrogen, Spectrum of, The Structure of the, Prof. A. Fowler, 881; Potassium, On the Spectrum of, in Connexion with the Red and Blue Spectrum of Argon, T. L. de Bruin and Prof. P. Zeeman, 352
Iraq, A Survey of the Fauna of: Mammals, Birds, Reptiles, etc. Made by Members of the Mesopotamia Expeditionary Force "D", 1915–1919, 854
Iridaceæ, Secondary Growth in Some, R. S. Adamson, 262
Iris, Essence of, The Study of, P. Langlais and J. Goby, 299
Irish Setter, The: its History and Training, Col. J. K. Millner, 428
Iron: and Steel: Specific and Latent Heats of, A. Mallock, 429; the Crystal Structure of, X-ray Studies on, A. Westgren and G. Pfragmen, 94; The Metallurgy of, 235; and Zinc, The Comparative Importance of, G. Bertrand and H. Nakamura, 299; Large Crystals of, 15; Ores and Iron Industry of China, The, including a Summary of the Iron Situation of the Circum-Pacific Region, F. R. Tegengren, 333; -Oxygen Equilibrium, The, Ferrous Alloys Research, Dr. W. Rosenhain and others, 554; Spectrum, The, Nagaoka and Sugiura, 447; Working in the Cameroons, L. W. G. Malcolm, 481
Irrigation in India, 1922–23, 549
Irwin River Valley, Western Australia, The Geology of the, W. G. Woolnough and J. L. Somerville, 300
Isis: The International Review devoted to the History of Science and Civilisation. Edited by Dr. G. Sarton, 404
Isostatic Compensation, Nature of, W. Bowie, 730
Isotopes and Spectra, Nagaoka, Sugiura, and Mishima, 699
Italian Power Plants, Films and Slides of, 97

Jail Administration in Ancient India, A. Thakur, 183
Jamaica, Deforestation in, Dr. A. W. Hill, 906
Japanese: Earthquake of Sept. 1, 1923, The: T. Kato, 70; Prof. Imamura, 484; Precursors of the, the late Prof. Omori, 291; *Journal of Astronomy and Geophysics, The*, 835; Rabbit, The, and Gametic Purity, W. E. Castle, 263
Johannesburg Refractor, The, Dr. Innes, 908

Joule's Laws of Electric Heating, W. W. Haldane Gee, 954
J-Phenomenon, The, Some Recent Researches on X-rays, Prof. C. G. Barkla, 753
Jurassic Ammonites of India, Dr. L. F. Spath, 695

Kalahari Desert, Former Fertility of the, Prof. E. H. L. Schwarz, 312
Kant: Immanuel, 1724–1924: Gedächtnisrede zur Einweihung des Grabmals in Auftrag der Albertus-Universität und der Stadt Königsberg in Preussen am 21 April 1924 im Dom zu Königsberg gehalten, A. von Harnack, 748; und seine Bedeutung für die Naturforschung der Gegenwart, Prof. J. von Kries, 748; und Einstein: Untersuchungen über das Verhältnis der modernen Erkenntnistheorie zur Relativitätstheorie, Dr. A. C. Elsbach, 748
Kant's Treatment of Causality, Dr. A. C. Ewing, 569
Kelvin: Centenary, The, 103; Lord: and the Royal Society of Edinburgh, Sir Alfred Ewing, 726; Appreciation of, Sir Oliver Lodge, 58; as professor in the Old College of Glasgow, Dr. D. Murray, 77; celebrations in Australia of the centenary of the birth of, memorial oration by Prof. H. S. Carslaw, 287; Life and Work, Dr. A. Russell, 104; William Thomson, 1824–1907, Dr. A. Russell, 77; Medal, presentation of the, to Prof. Elihu Thomson, 103; Oration, The, Sir J. J. Thomson, 103
Kemp Fibres in the Merino Sheep, Prof. Duerden and Miss Ritchie, 799
Kerguelen, The Archipelago of, The Grained Eruptive Rocks of, A. Lacroix, 299
Kerr Effect in Optically Active Liquids, The, R. de Mallemann, 663
Kerr's Electro-optical Effect in Gases, G. Szivessy, 516
Kilima Njaro, The People of, 711
Kilimanjaro and its People: a History of the Wachagga, their Laws, Customs, and Legends, together with Some Account of the Highest Mountain in Africa, Hon. Charles Dundas, 711
Kirstenbosch, South African Botany and Nature Reserves, Prof. R. H. Compton, 802
Kitāb al-'ilm al-muktasab fī ziṟā'at aḍh-ḍhahab: Book of Knowledge acquired concerning the Cultivation of Gold, Abu'l-Qāsim Muḥammad ibn Aḥmad al-Irāqī. The Arabic text edited with a translation and introduction by E. J. Holmyard, 307
Klimate der Erde: Die, Grundriss der Klimakunde, Prof. W. Köppen, 44
Knoll-Reefs and the Craven Faults, Prof. E. J. Garwood and Miss Edith Goodyear, 482
Knowledge: The First Days of, as Narrated quite simply for Young Readers, F. A. Kummer. (The Earth's Story. Vol. II.), 533
Kolloidchemie: als Hilfswissenschaft der Mineralogie und Lagerstättenlehre und ihre Anwendung auf die metasomatischen Blei-Zink-Lagerstätten, Die, Dr. F. Bernauer, 568; und Biologie. Zugleich dritte Auflage von Kapillarchemie und Physiologie, Prof. H. Freundlich, 781
Kolloiden, Licht und Farbe in: eine phänomenologische Monographie, Prof. Wo. Ostwald. Erster Teil, 672
Krakatau, The Ants of, Prof. W. M. Wheeler, 63

Labels, Descriptive, for Botanic Gardens, H. Gilbert-Carter, 748
Labour, Science and: Major A. G. Church, 89; Prof. H. Levy, 849; being the Principal Addresses at the Conference on Science and Labour held in London on 30th and 31st May 1924. Edited by T. Ll. Humberstone, 849
La Courtine, The Propagation of the Explosive Waves resulting from the Experiments at, A. Nodon, 32
Lagrange's Series, Note on, N. Nielsen, 845
L'Hérédité, Prof. É. Guyénot, 307
L'Homme préhistorique dans l'Europe centrale: Primeval Man in Central Europe, Prof. P. Goessler, 410
Lake: Level in Relation to Rainfall and Sunspots, Dr. F. Dixey, 659; Lucerne, The Hydrogen Ion Concentration of the Waters of, J. T. Saunders, 810; Victoria and the Flow of the Yala River, N. L. Silvester; C. E. P. Brooks, 536
Lamprey, European, The Specific Value of the Three Kinds of, and the Young Stages of *Petromyzon fluviatilis*, L. Leger, 774
Land: and Fresh Water Vertebrate Animals of the United States (exclusive of Birds), A Manual of, Prof. H. S. Pratt, 533; Vertebrates, The Origin of, Prof. E. S. Goodrich, 935
Landslide in Austria, A, 325
Landslides near Picton and Notes on the Local Vegetation, R. H. Cambage, 956
Landslips in Italy, R. Almagia, 730
Laterally Loaded Struts, T. W. Greene, 328
Lathræa clandestina, The Seed Dispersal of, J. L. North, 657
Lathyrus odoratus, Pollen Development in, Miss J. Latter, 917
Lead: Electrolytic Separation of Copper, Antimony, and Bismuth from, A. Lassieur, 667; in the Organism, The Circulation of, J. A. Christiansen, G. Hevesy, and S. Lomholt, 336; Tetra-ethyl, The Decomposition of, and its Application to Internal Combustion Motors, P. Jolibois and G. Normand, 211
Leaf: Cells, Permeability of, Prof. H. H. Dixon, 146, 552; -mould, Prof. J. B. Farmer, 87
League of Nations, The Commission for Intellectual Co-operation of the, Proposal to, as to Science and War, 584
Leaves, Variegation in, S. Funaoka; O. Renner, 765
Leeds University: gift by A. Seymour-Jones of books to the Leather Industries Department; new lectureship in medical radiology and electro-therapeutics, Dr. Scargill and Dr. Cooper joint lecturers; W. Davies appointed demonstrator in engineering, 29; Prof. J. B. Baillie appointed Vice-Chancellor, 144; Dr. A. Haworth appointed lecturer in chemical pathology, 180; J. R. R. Tolkien appointed professor of English language; Dr. C. E. Gough appointed to the chair of German, and Dr. S. Brodetsky to the chair of applied mathematics, 208; Extension Lectures, 260; Dr. F. S. Fowweather appointed lecturer in chemical pathology, 701; The Smithells Fund, 771; the title of emeritus professor conferred upon Prof. J. B. Cohen; J. W. Baker appointed a demonstrator in organic chemistry, 807; tribute to Prof. A. Smithells, 841; Calendar for 1924–25, 843; Celebrations, The, 941
Left-handedness, Stammer, and Squint, Dr. W. S. Inman, 392
Lehigh University, establishment of an institute of research at, 797
Leicester Museum, Art Gallery, and Library, appointment of Miss F. A. Rogers as guide demonstrator, 202
Leidy, Joseph, The Influence of, on Science, Dr. E. S. Morse and others, 20
Leitfossilien aus dem Pflanzen- und Tierreich in systematischen Anordnung, Prof. J. Felix. Zweite Auflage, 713
Le Monde social des fourmis, comparé à celui de l'homme, Prof. A. Forel. 5 vols., 79
Lenses, a Combination of, The Back Vertex Power of, T. Smith, 844
Leptoplastus salteri Callaway, and of other Trilobites, Development of, F. Raw, 145
Lesser Antilles, The Formation of the, Prof. W. M. Davis, 263
Leucocyte in Health and Disease, The, being an Enquiry into Certain Phases of Leucocytic Activity, C. J. Bond, 784
Libyan Desert, Explorations in the, Hassenein Bey; Dr. J. Ball, 799
Life: a Book for Elementary Students, Sir Arthur E. Shipley, 6; -Control, Prof. F. W. Gamble, 249; Science and, 185; The Unity of, 6
Light: A Treatise on, Dr. R. A. Houstoun. New edition, 855; Artificial, Effect of, on the Growth of Plants, R. B. Harvey and others, 732; emitted from Solidified Gases, The, and its Relation to Cosmic Phenomena, Prof. L. Vegard, 357; Primary Standards of, Dr. Ives; M. Fleury, 329; The Biological Action of, 901; The Diffusion of, by Krypton and Xenon,

J. Cabannes and A. Lepape, 371 ; The Structure of, Sir J. J. Thomson, 624 ; The Total Reflection of, Sir Arthur Schuster, 772 ; Velocity of, New Measurement of the, Prof. A. A. Michelson, 831
Lighting : Factory and School, L. B. Marks, 330 ; Good, Lieb, Merrill, and Powell, 330 ; Street, H. T. Harrison, 329
Lightning : Ball, Dr. A. W. Crossley, 10 ; Flash, Noise of the, E. Mathias, 396 ; Photographs of, Dr. G. C. Simpson, 433 ; Unusual Display of, in Canada, J. W. Hayward, 513
Lime, and Magnesia : F. A. Freeth, 852 ; The Chemistry, Manufacture, and Uses of the Oxides, Hydroxides, and Carbonates of Calcium and Magnesium, N. V. S. Knibbs, 852 ; as a Constituent of Certain Important Rock-forming Minerals, A. Brammall, 774
Limestones, The Origin of, Dr. T. W. Vaughan ; T. Crook, 733
Line and Band Spectra, The Isotope Effect in, Dr. R. S. Mulliken, 89
Liquid : Air in Mine Rescue Apparatus, 543 ; Crystals, Soap Solutions and X-rays, Prof. J. W. McBain, 49
Liquids at their Boiling-points, The Viscosities of, D. B. Macleod, 883
Lister (Lord), a statue of, unveiled at Glasgow, 476
Literature, Science and, 399
Lithium : Spectrum of, New Lines in the, M. Morand, 172 ; Vapour, Absorption of, Prof. A. L. Narayan and D. Gunnaiya, 31
Lithobius : *forficatus*, Oogenesis in, Miss S. D. King, 52, 954 ; V. Nath, 159, 810
Liverpool : Astronomical Society, Annual Report, 1923–1924, 325 ; University, bequest to, by Prof. G. A. J. Cole, 180
Liverworts as Fossils in the Carboniferous Rocks of England, The Existence of, J. Walton, 594
Load Line (Zones) Committee, Report of the, 391
Locustana pardalina (Walker), The Spermatogenesis of, D. J. Malan and D. E. Malan, 336
Loggerhead turtle, a, found at Skye, 443
London : Continued Education in, Guide to, 486 ; County Council : Handbook of Lectures and Classes for Teachers, 334 ; Technical and Evening Classes of the, 451 ; Electric Railway, Extension of the, An Automatic Sub-station in the, 287 ; Mathematical Society, appointment of officers and council of the, 762 ; (Royal Free Hospital) School of Medicine for Women, Jubilee Celebrations of the, 653 ; University : Prof. E. A. Gardner elected vice-chancellor ; Dr. B. B. Baker appointed professor of mathematics at the Royal Holloway College ; Dr. C. L. Burt appointed professor of education at the London Day Training College, 29 ; conferment upon Dr. C. C. Choyce of the title of professor of surgery, upon H. G. Smith that of reader in geology, upon Prof. O. W. Richardson that of professor of physics, 29 ; gift by Sir Hermann Gollancz of library, and by Mrs. Preedy of books ; conferment of doctorates, 29 ; gift to the Middlesex Hospital Medical School by S. A. Courtauld, 71 ; the forthcoming centenary of University College, 106 ; Dr. M. Ginsberg appointed reader in sociology at the London School of Economics ; the title of professor conferred on J. T. MacGregor-Morris ; that of reader in physical chemistry on W. E. Garner ; that of reader in public administration on H. B. Lees-Smith, and that of emeritus professor on Prof. J. W. Adamson ; resignation of Prof. H. R. Kenwood ; conferment of doctorates, 180 ; Dr. A. W. M. Ellis appointed professor of medicine at the London Hospital Medical College, and Dr. E. V. Appleton to the Wheatstone chair of physics at King's College ; award of doctorates, 208 ; Guide and University Correspondence College Calendar, 1924–25, 486 ; appointment of a committee on principal changes most needed ; resolution in reply to a communication from the Board of Education, 593 ; Prof. S. L. Loney elected chairman of Convocation ; Sir Josiah Stamp elected representative on the Senate of the Registered Graduates in Science, 629 ; Dr. T. Yeates appointed to the S. A. Courtauld chair of anatomy at the Middlesex Hospital Medical School ; the Sir John William Lubbock Memorial prize awarded to Miss E. M. Jones ; conferment of doctorates, 665 ; gift by Miss Mary Brodrick for an annual prize in geography ; new University travelling scholarships to be instituted ; conferment of doctorates ; Dr. G. V. Anrep awarded the William Julius Mickle fellowship, 807 ; Dr. F. L. Hopwood appointed professor of physics at St. Bartholomew's Hospital Medical College ; the title of professor of botany conferred upon Dr. F. E. Fritsch ; the title of reader in human embryology conferred upon Dr. R. J. Gladstone, 807 ; the title of professor of anatomy conferred on Mrs. M. F. L. Keene, 842 ; conferment of doctorates, 879, 915
" Londoner's Education, The," 181
Long Life's Work, A : an Autobiography, Sir Archibald Geikie, 114
Lophyrus pini, The Stage in which Dopa is formed in the Cocoon of, I. Sciacchitano, 184
Lord Howe Island, Foraminifera of, E. Heron-Allen and A. Earland, 101
Low : Temperature Carbonisation, Parker Plant for, 914 ; Voltage Arcs, Explanation of Abnormal, Prof. K. T. Compton and C. H. Eckart, 51
Lucerne (*Medicago sativa*), Seed Inoculation of, and its Relation to the Motility of the Nodula Organism in Soil, H. G. Thornton and N. Gangulee, 932
Luminescence of Nitrogen, Argon, and other Condensed Gases at Very Low Temperatures, The, Prof. J. C. McLennan and G. M. Shrum, 30
Luminous Spectra of Solid Nitrogen, The, etc., Prof. L. Vegard, 211
Lunar : Eclipse of August 14, The Total, 203 ; Eclipses, Total, W. J. Fisher, 62 ; Periodicity in Reproduction, H. Munro Fox, 555
Lunge and Keane's Technical Methods of Chemical Analysis. New edition. Edited by Dr. C. A. Keane and P. C. L. Thorne. Vol. I., 640
β Lyræ, Miss M. A. Blagg, 254

McGill University, Dr. R. F. Ruttan appointed dean of the Faculty of Graduate Studies and Research in, 98
McLeod Gauge, A Substitute for the, H. A. Fleuss, 12 ; Dr. N. R. Campbell, J. W. Ryde, and B. P. Dudding, 276, 467
Madagascar (the Antsirabe Basin) and of Reunion, The Radioactivity of Some Thermal Springs of, C. Moureu, A. Lepape, and H. Moureu, 299
Madeira Islands, The Spiders of the, Prof. T. D. A. Cockerell, 11
Madras, the Presidency of, Flora of, J. S. Gamble. Part 6, 821
Magellanic Cloud, The Lesser, Prof. H. Shapley, 100
Magic Squares, Hyper and Ornate, 15th and 16th Orders, Major J. C. Burnett, 821
Magnesian Limestone of Fulwell, The Micropetrography of the Structures of the, G. Abbott and W. A. Richardson, 109
Magnesium Hydroxide and Carbonate, Crystalline Lattices of, G. R. Levi and A. Ferrari, 262
Magnetic : Fields, Intense, The Production of Very, Dr. T. F. Wall, 432, 898 ; Radium-*C* β-ray Spectrum, The High Energy Groups of the, C. D. Ellis, 75
Magnetite in Diamond, An Inclusion of, Dr. L. J. Spencer, 774
Magneton Numbers and Atomic Structure, Dr. J. Dorfmann, 24
Malaria, The Transmission of, Prof. B. Grassi, 262
Malarial Treatment of General Paralysis, The, 164 ; Prof. W. Yorke, 615
Malay Peninsula : Aborigines of the, I. H. N. Evans, 445 ; The Flora of the, H. N. Ridley. Vols. 2 and 3, 84
Malic Acid : and Copper, The Compounds of, E. Darmois, 32 ; and Molybdic Acid, The Electrometric Study of the Acidity of Mixtures of, E. Darmois and A. Honnelaitre, 147
Malta, Excavations in, M. A. Murray. Part I. With a chapter by G. C. Thompson, 462
Mammalian Erythrocyte, The Balloon-like Structure of the, E. Ponder, 809

Man: before History: a Short Account of Prehistoric Times, Mary E. Boyle, 410; Making of, a Study in Evolution, Sir Oliver Lodge, 408; The Ascent of, F. S. Marvin, 408; The Evolution of, Essays, Prof. G. Elliot Smith, 410; The Ancestors of, Prof. H. F. Osborn, 481
Manchester: Literary and Philosophical Society, Early History of the, F. Nicholson, 762; Municipal College of Technology, reductions in fees for degree and certificate courses, 630; University: E. A. Milne appointed Beyer professor of applied mathematics, 144; J. H. Ray appointed reader in surgical pathology, P. R. Wrigley and G. Wright lecturers in surgical pathology, W. Baker and B. Cavanagh assistant lecturers in chemistry, and Dr. P. W. Clutterbuck demonstrator in physiological chemistry; Prof. S. J. Hickson reappointed to the chair of zoology, 180; gift for the endowment of a scholarship; Dr. T. M. Cherry appointed associate professor of applied mathematics, J. B. M. Hay assistant lecturer in engineering, Miss Hilda Linford demonstrator in human physiology, and E. N. Willmer demonstrator in experimental physiology, 209; resignation of Dr. W. H. Wood and H. G. Jordan; J. Orr appointed adviser in agricultural economics with the status of a senior lecturer, 952
Manganese: in Plants, Importance of, J. S. McHargue, 64; The Electro-deposition of, Prof. A. J. Allmand and A. N. Campbell, 182
Marine: *Observer*, The, September, 389; November, 763; Plankton, The, with special reference to Investigations made at Port Erin, Isle of Man, during 1907–1914, a Handbook for Students and Amateur Workers, Dr. J. Johnstone, A. Scott, and H. C. Chadwick, 497; -propelling Machinery, The Trend of Development of, Eng. Vice-Adml. Sir George G. Goodwin, 792; Structures, their Deterioration and Prevention. Report of the Committee on Marine Piling Investigations of the Division of Engineering and Industrial Research of the National Research Council, W. G. Atwood and A. A. Johnson and others, 744
Marquesan Somatology with Comparative Notes on Samoa and Tonga, L. R. Sullivan, 295
Marquesas Islands, The Material Culture of the, R. Linton, 295
Mars: Dr. W. H. Steavenson, 283; M. Antoniadi, 586; Cloud-capped Protuberances on, F. Baldet and E. M. Antoniadi, 810; Observations of, E. M. Antoniadi; M. Quénisset, 836; Some Changes recently observed on, E. M. Antoniadi, 702; The Occultation of, by the Moon on November 5, 1924, G. Bigourdan, 845; The Opposition of, 254; The Temperature of, C. T. Chase, 934
Martian Photography, W. H. Wright; Prof. E. C. Slipher; Prof. R. Trumpler, 798
Mass, Secular Diminution of, The Effect of, Dr. J. H. Jeans, 764
Mastotermes darwiniensis Froggatt (Isoptera), G. F. Hill, 523
Mathematical: Congress, International, 26; at Toronto, Prof. J. C. Fields elected president, 590; Physics: The Evolution of, being the Rouse Ball Lecture for 1924, Dr. H. Lamb, 460
Mathematicians and Physics, Prof. Piaggio, 690
Mathematics: at British Universities, a Beginner in Relativity, 194; for Engineers, Prof. S. Brodetsky, 674; History of, Vol. 1, Dr. D. E. Smith, 707; in France, The Teaching of, Prof. S. Brodetsky, 45
Mathématiques: La Composition de, dans l'examen d'admission à l'École Polytechnique de 1901 à 1921, F. Michel et M. Potron, 45; spéciales, Cours complet de, Prof. J. Haag. Tome 3, 45
Matter: and Change: an Introduction to Physical and Chemical Science, W. C. D. Whetham, 710; and the Atom, The New Theories of, Prof. A. Berthoud. Translated by Eden and Cedar Paul, 928; The Structure of, Dr. J. A. Cranston, 856; What is, Prof. H. Wehl, 256
Measuring very Small Capacities, A Method of, L. Hartshorn, 146
Mecànica Clàssica i Relativista, Qüestions de: Conferències donades el Gener de 1921, Prof. T. Levi-Civita, 339
Mécanique: Les Axiomes de la (Examen critique): Note sur la propagation de la lumière, Prof. P. Painlévé, 339; rationnelle, Leçons de, professées à l'École des Mines et de Métallurgie Faculté technique du Hainaut à Mons, Prof. F. Bouny. Tome I., 674
Meccanica, I principî della, alla luce della critica, G. Casazza, 571
Mechanical Flight, The Coming of Age of, 867
Mechanics, A School, C. V. Durell. Part I., 714
Medical: Education, Methods and Problems of. First series, 907; Protozoology, Prof. R. W. Hegner, 101; Research Council, Prof. E. P. Cathcart appointed a member of the, 727; Women, Pioneer, Mrs. F. Miller, 736; Zoology: Outlines of, with special reference to Laboratory and Field Diagnosis, Prof. R. W. Hegner, Prof. W. W. Cort, and F. M. Root, 893
Medicinal Products, British Dyestuffs Corporation, Ltd., 836
Medicine: Magic and Religion: the FitzPatrick Lectures delivered before the Royal College of Physicians of London in 1915 and 1916, Dr. W. H. R. Rivers, 563; Primitive, W. J. Perry, 563; The Abram's Cult in, 525; The Debt of Science to, Sir Archibald Garrod, 728; The Relation of Philosophy to, Prof. H. Oertel, 907
Melaleuca: *erubescens* (Otto) and *M. hypericifolia* (Smith), The Essential Oils of, A. R. Penfold, 919; Notes on, with Description of Two New Species and a New Variety, E. Cheel, 919
Melanesia, Eastern, Ceremonial Exchange in, R. Lenoir, 694
Mellon Institute, University of Pittsburgh, Report for 1923–24, 486
Memory, Theories of, Dr. Beatrice Edgell, 893
Mendelian Studies, 305
Mendeliana, Studia: ad centesimum diem natalem Gregorii Mendelii a grata patria celebrandum, 305
Mendelism and Evolution: J. T. Cunningham, 9, 537; C. Dover, 10; J. S. Huxley, 464
Mensch und Ameise, Prof. A. Forel, 79
Mentally Defective, The, Miss Nelly Burdett, 288
Menthol and Neomenthol, The Isomerism of, G. Vavon and A. Couderc, 396
Merchant Venturers Technical College, Bristol, Prof. A. Robertson appointed principal of the, 700
Mercuric Oxide, Forms of, G. R. Levi, 767
Mercury: a Morning Star, 444; and Bismuth, Isotopes of, and the Satellites of their Spectral Lines, Prof. H. N. Nagaoka, 245; and Helium, J. J. Manley, 861; Arc: Distribution of Energy in the Spectrum of a, G. Athanasiu, 111, 205; Rectifier, Experiments on a, W. Schottky and J. von Issendorff, 588; into Gold, The Reported Transmutation of, 197; Prof. F. Soddy, 244; Line λ2270 A., On the, Dr. T. Takamine and M. Fukuda, 382; the Band Spectrum of, Origin of, E. Hultén, 594; The Direct Formation of the Oxychlorides, Oxybromides, and Oxyiodides of, H. Pélabon, 32
Mesosuchus browni, Watson, A Skull and Partial Skeleton of, S. H. Haughton, 262
Mesothorium 2, The β-ray Spectrum of, D. H. Black, 773
Metal: Cutting under Water, J. B. Polland, 870; Spraying and Sprayed Metal, T. H. Turner and W. E. Ballard, 522; Systems, Application of the Ideal Solubility Curve to the Interpretation of Equilibrium Diagrams in, D. H. Andrews and J. Johnston, 487
Metallic: Crystals, Single, A New Method for Producing, I. Obreimow and L. Schubnikow, 173; Electrolytic Deposits, Fibrous Structure in, R. Glocke and E. Kaupp, 137; Vapours: Conductivity of, Dr. E. Zachmann, 368; Some, Absorption Spectra of, Prof. A. L. Narayan, G. Subrahmaniam, D. Gunnaiya, and K. Rangadhamarao, 194
Metallurgy: Medieval, M. L. Becker, 837; Theoretical, R. S. Dean, 892
Metals: Institute of: The Growing Needs of the, Prof. T. Turner, 390; Journal of the, Vol. XXXI., edited by G. Shaw Scott, 640; Specific Heats of, Measuring the, at High Temperatures, K. K. Smith and L. I. Bockstahler, 846; The Fatigue of, Profs. H. F. Moore and T. M. Jasper, 137

Metamorphic Zones in the Southern Highlands of Scotland, A Preliminary Survey of, C. E. Tilley, 74
Meteoric Iron, A, from Four Corners, San Juan County, New Mexico, G. P. Merrill, 559
Meteorite, A Stony, from Anthony, Harper County, Kansas, etc., G. P. Merrill, 559
Meteorites, "Bitumen" in, Dr. P. E. Spielmann, 276
Meteorological: Data over the Oceans, 23; Literature, A Bibliography of, No. 6, 945
Meteorology: Antarctic, 853; "in Education," 169
Meteors, The November, W. F. Denning, 693
Methane: from Coal Gas, Synthesis of, 102; from Water Gas, Synthesis of, 137
Methyl: Alcohol, The Dissociation Constant of, N. Bjerrum, Miss Unmack, and L. Zechmeister, 147; Formate, The Sudden Pyrogenic Decomposition of, and the Principle of Minimum Molecular Deformation, J. A. Muller and Mlle. E. Peytral, 774; Oxide: Revision of the Compressibility of, and the Molecular Weight of this Gas, T. Batuecas, 631; Revision of the Weight of the Normal Litre of, T. Batuecas, 452
Metric Weights and Measures, 833
Mexico, Valley of, Expedition to the, 170
Mica, The Dielectric Properties of, D. W. Dye and L. Hartshorn, 844
Mice, White, Inheritance of a Retinal Abnormality in, C. E. Keeler, 559
Michelson's Experiment, The Possibility of Thermal Disturbance in, E. Brylinski, 767
Mickle, Charles, Prize, awarded to Sir James Mackenzie, 905
"Micrographia," R. Hooke, The 260th Anniversary of the Publication of, 795
Microscope: A Pocket, Ogilvy and Co., 839; A Portable, R. and J. Beck, Ltd., 517; The, Part II. An Advanced Handbook: a Sequel to "The Microscope, a Simple Handbook," C. Beck, 571
Microscopes: C. Baker's Catalogue of, 514; Metallurgical, J. Swift and Sons, 447; New Devices for, Ogilvy and Co., 173
Microscopic Objects, Catalogue of, W. Watson and Sons, Ltd., 908
Microseismic Movements at Strasbourg, J. Lacoste, 631
Microseisms: and Storm Forecasts, E. P. Harrison, 645; associated with the Incidence of the South-west Monsoon, S. K. Banerji, 576
Midland Agricultural and Dairy College, H. T. Cranfield appointed adviser in agricultural chemistry for the Midland Colleges served by the, 771
Migration may be visible or invisible, T. A. Coward, 883
Mikrokosmos, Entdeckte Verborgenheiten aus dem Alltagsgetriebe des, Prof. P. Lindner, 570
Milan University, foundation of a chair in social eugenics in, Prof. S. Patellani first professor, 513
Milk: Cattle, Recording of, Mackintosh, 206; -recording, B. A. Sanders, 206
Mimosa pudica, Conduction of Excitation in Stem and Leaf of, R. Snow, 626
Mind construct? What does the, Prof. A. D. Lindsay, 738
Mine: Rescue Apparatus Research Committee, Third and Final Report of the, 543; Ventilation: Theory and Practice of, a Text-book for Students and a Book of Reference for Managers and Under-Managers, 7
Mineral Separation, Dielectric, Prof. S. J. Truscott, 793
Mineralogists recently deceased, biographical notices of (second series), Dr. L. J. Spencer, 774
Minerals of the Pre-Cambrian in Canada, Dr. C. V. Corless, 392
Miners' Flame Safety Lamp: Gauzes, 591; fitted with Open Mesh Gauzes, Report on Tests of, Capt. C. B. M. Platt, 591
Mining, Safe, A Necessary Condition for, in an Inflammable Atmosphere, E. Audibert, 774
Mira Ceti, Dr. W. J. S. Lockyer, 254
Mixed Individuals formed from the Ex-conjugants, after True Conjugation in *Criptochilum echini* Maupas, and the Origin of the Gametogens, A. Russo, 262; Metallic Vapours, Absorption Spectra of, S. Barratt, 827
Molecular: Fields, The Determination of, Pts. I. and II., J. E. Jones, 74; III., J. E. Jones, 881; Transpositions, Mme. Pauline Ramart, 335
Molecules: The Electric Moments of, C. P. Smyth, 801; The Structure of, in Relation to their Optical Anisotropy, Prof. C. V. Raman, 49
Molluscan: Collections, Results of Roy Bell's, C. Iredale, 300; Problems, 255
Molten Metal Alloys, Electrolytic Conductivity in, R. Kremann and R. Gruber-Rehenburg, 300
Molybdenite, The Change of Resistance of, due to Light, S. L. Martin, 883
Molybdenum Kα rays, The Wave-length of, when scattered by Light Elements, Prof. A. H. Compton and Y. H. Woo, 264
Mongol in our Midst, The: a Study of Man and his Three Faces, Dr. F. G. Crookshank, 605
Monilia, A Species of, associated with Severe Anæmia, L. Weld Smith, 656
Monotropitine, The Hydrolysis of, by a Ferment, M. Bridel, 845
Moon: Element, The: an Introduction to the Wonders of Selenium, Dr. E. E. Fournier d'Albe, 47; Observations of the, Dr. H. Spencer Jones, 908
Moorland Plants, Ecology of, Prof. J. H. Priestley and others, 698
Morocco Grand Atlas, The Alpine Vegetation of the, R. Maire, 559
Morphine and Heroin, the supply of, to drug addicts, appointment of a committee on, 549
Morphologie générale. Membres et ceintures des vertébrés tétrapodes: Critique morphologique du transformisme, Prof. L. Vialleton, 928
Mosquito Control at Hayling Island, 171
Mosses, British, and how to Identify them, J. H. Crabtree, 306
Motor Car, The: its Birth, its Present, and its Future, Col. R. E. Crompton, 833
Mound Exploration in California, Ll. L. Loud, 729
Mountain: Sickness, Prof. J. Barcroft, 90; Structure, Prof. Schuchert and others, 394
Moustiques de l'Afrique mineure, Les, de l'Égypte et de la Syrie, E. Séguy, 712
Moxon Gold Medal, the, presented to Sir Leonard Rogers, 654
Munich Technical Hochschule, Prof. A. von Parseval nominated professor of aviation at the, 915
Münster University, Dr. H. Többen appointed professor of forensic medicine, and Dr. H. Freund professor of pharmacology, 843
Murray River Natives, Mourning Caps of, E. R. Waite, 63
Muscle, Shortening or Lengthening, Thermodynamic Phenomena exhibited in a, R. Azuma, 73
Muscular Contraction, The Dynamics of, Prof. A. V. Hill and H. S. Gasser, 73
Museum of Practical Geology, The, 167
Museums: and the British Empire, Dr. H. Bolton, 149; Loans to, 18
Musical Sounds always Harmonic? Are the Overtones of, Dr. H. Hartridge, 75
Mycological: Conference, The Imperial, 207; Investigations, Application of the Results of, Dr. Shaw and others, 208
Myrmecophiles, Two Extraordinary Larval, from Panama, W. M. Wheeler, 264

Naphthalene, The Use of, as a Fumigant in the Control of Red Spider and other Pests in Cucumber Houses, E. R. Speyer, 193
Natal Museum Pictorial Post-cards, 944
National: Fruit and Cider Institute: Annual Report of the, 332; Field Day of the, 134; Physical Laboratory: Teddington, Annual Visitation, 67; The, Collected Researches, Vol. 17, 950; Poultry Institute, Prof. W. C. Thompson appointed director of the, 727
Native, The Education of the, W. G. Bennie, 802
Natural: and Artificial Selection, A Mathematical Theory of, Part II., J. B. S. Haldane, 182; Gas Industry, 327; History: A New, 152; Society of Northumberland, Durham, and Newcastle-upon-Tyne, Report for 1923–24, 871; Vegetation of the Empire in its Ecological Aspect, Study of, A. G. Tansley and others, 294

Nature : and Man in Tropical Africa, 420 ; organique, Le Principe constitutif de la, É. Jung, 822 ; the Protection of, Central Correlating Committee for, Establishment of a, 477 ; -world of London, The, W. Johnson, I. : Trees and Plants, 306
Navy, Hydrographer of the, Capt. H. P. Douglas appointed, 251
Neanderthal Man and Grimaldi Man : their Rôle in the Evolution of Mankind, Prof. R. Verneau, 899
Nebulæ : Spiral and Structureless, J. H. Reynolds, 431 ; The Spiral, Dr. K. Lundmark, 586
Nebulium Lines, Spectral Theory and the Origin of the, S. Rosseland, 859
Nectar of Flowers, The, T. Steel, 595
Nematodes, Free-living, from Suez, Final Report on, H. Micoletzky, 184
Nephelometer, A New Type of, R. Kingslake, 844
Nephelometry, A. Pollard, 844
Nephrops, Feeding and Digestion in, C. M. Yonge, 63
Netherland Indies : Humidity in the, Dr. C. Braak, 947 ; Temperature in the, Dr. C. Braak, 101
Neutralisation, The Theory of, T. Smith, 844
New Caledonia, The Inhabitants of, and Neanderthal Man, Prof. F. Sarasin, 291
Newcomen Society for the Study of the History of Engineering and Technology, The : Transactions, Vol. 3, 1922–1923, 925
New South Wales : Evidence of a Negative Movement of the Strand Line of 400 Feet in, T. H. Smith and T. Iredale, 883 ; The Freshwater Entomostraca of, Pt. IV., Marguerite Henry, 212 ; Two New Thrips-galls and their Inhabitants from, W. D. van Leeuwen and H. H. Karny, 300
Newton, Sir Isaac, and his Work, Prof. F. Cajori, 60
New York, Bequest for the Establishment of Museums in, H. R. Towne, 654
New Zealand : Astronomical Society, Prof. A. W. Bickerton elected an honorary member of the, 834 ; Government, Grants from the, for Schools of Forestry, 486 ; The Atlantic Salmon in, W. J. Phillipps, 89
Nickel : for Coinage, The Working of, Sir Thomas K. Rose and J. H. Watson, 488 ; Steels, Relation between the Elastic Tension and the Magnetic Behaviour of, in the Neighbourhood of the Transformation Point, W. Del Regno, 667 ; very pure, The Magnetic Quality of, Ada M. Malcolm, 110
Nigeria, Southern, Life in : the Magic, Beliefs and Customs of the Ibibio Tribe, P. A. Talbot, 43
Nigerian Coal Measures, A. D. N. Bain, 64
Nigerians, Southern, 43
Night Sky, The Light of the : its Intensity Variations when analysed by Colour Filters, Lord Rayleigh, 30
Nitrifying Power of Arable Soil, Measurement of the, R. Perotti and G. Grandis, 262
Nitrogen : Active, Lord Rayleigh, 717 ; Prof. R. T. Birge, 642 ; and Uranium, Dr. P. D. Foote, 789 ; Solid, Luminescence of, and the Auroral Spectrum, Prof. L. Vegard, 715
Nitrous Oxide : and Hydrogen, The Kinetics of the Interaction of, C. N. Hinshelwood, 738 ; The Homogeneous Thermal Decomposition of, C. N. Hinshelwood and R. E. Burk, 738
Nobel prizes for chemistry and physics for 1924, postponement of the award of the, 762
Non-university Resources for Graduate Study and Research, President Wilbur, 261
Nopinene, The Oxidation of, by Permanganate, G. Brus, 559
Northampton Polytechnic Institute, S. C. Laws appointed principal, 144
North Greenland Coast, Fungi from, J. Lind, 909
North of Scotland College of Agriculture, Calendar of the, 665
Norwich, Castle Museum, gift to, of a collection of British birds by G. H. Gurney, 654
Notgemeinschaft der deutschen Wissenschaft, Third Report of the, 441
Numerical Data, Co-ordination of, 377
Nutrition, Human, Quantitative Problems in, Report on the Nutrition of Miners and their Families, 332
l'Observatoire Royal de Belgique, Annuaire de, 1925, 325
"Observer's Primer, The," 619
Occupational Groupings, The Mapping of, A. Farquharson, 391
Ocean Tides, Earth Tides and, Dr. J. W. Evans, 49 ; and Local Geology, W. D. Lambert, 572 ; Dr. J. W. Evans, 749
Oceanic Waters, The Surface Layers of, J. Thoulet, 102
Oceanography, An Introduction to, with special reference to Geography and Geophysics, Prof. J. Johnstone, 306
O. edulis, Sex Change and Breeding in the Native Oyster, Dr. J. H. Orton, 191
Oil : -cracking, 629 ; in France, discovery of, 761 ; Production, Statistics of, G. B. Richardson, 947
Oils, Fatty, The Pyrogenesis of, Prof. A. Maihle, 619
Oligochaet, A Rare British, Rev. H. Friend, 124
Oligochæte Worms, Protozoan Parasites of, Dr. Doris L. MacKinnon and Miss D. Ines Adam, 481
Olive Oil, 801
Onslow, Huia : a Memoir, Muriel Onslow, 926
Oologist, The Comparative, No. 1, 388
Opalescence at and near the Critical Point, A. Audaut, 255
Optical : Diffraction, Some Problems in the Theory of, E. T. Hanson, 631 ; Doublets and Triplets, The Intervals between the, Prof. A. Landé, 292 ; Glass, History of, 657 ; Interference Experiments with Multiple Sources, J. J. Dowling and J. A. C. Teegan, 146 ; Planetarium at Munich, The, 937 ; Records and Relativity, Prof. C. Lloyd Morgan, 577 ; Prof. H. Wildon Carr ; Prof. C. Lloyd Morgan, 681 ; Separations and Atomic Numbers, A. C. Menzies, 861 ; Systems, Aberration of, the Determination of the, Modification of the Method of Zones (Ritchey) for, J. Cojan, 811
Optics : Research in, 950 ; the Theory of, An Introduction to, Sir Arthur Schuster. Third edition, revised and enlarged by the Author and Prof. J. W. Nicholson, 48
Orchard Heating in the United States, 370
Orchis : *Fuchsii* (Druce) a Valid Species of Orchidaceæ ? Is, Dr. H. O. Forbes, 610 ; *latifolia*, The Seed of, T. A. Dymes, 109
Ordnance Maps, Exercises on, Selected and Arranged by C. H. Cox, 308
Ore : Dressing : Principles and Practice, Prof. T. Simons, 856 ; Magmas, The : a Series of Essays on Ore Deposition, J. E. Spurr, 2 vols., 604
Ores : as Igneous Rocks, 604 ; The Origin of, Dr. R. H. Rastall, 12
Organ-pipes of Unusual Shapes, On the Vibrations of Air in, J. A. Aldis, 309 ; Dr. E. T. Paris, 465 ; W. E. Benton, 573, 787
Organic : Chemicals for Research Work, etc., List of, of the British Dyestuffs Corporation, Ltd., 203 ; Salts and their Sodium Salts, The Comparative Adsorption of some, C. Fromageot and R. Wurmser, 845 ; Substances, Effect of Pressure on, N. A. Pushin and E. V. Grebenshchikov, 874 ; Syntheses : an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals, vol. 3, H. T. Clarke, 606
Organismen, Geschichte der, Prof. V. Franz, 889
Organo-aluminium Compounds, Mixed, V. Grignard and R. Jenkins, 262
Oriental : Research, Historical Tradition and, Prof. J. H. Breasted, 755 ; Prehistory, J. de Morgan, 22
Orrery, A New Form of, Carl Zeiss, 203
Ortho-stereoscopy, Wide-angle : its Optical, Practical, and Psychological Advantages, Col. L. E. W. van Albada, 75
Osmotic Pressure in Terrestrial Invertebrates, A. Clementi, 148
Osmunda, Abnormal Morphology of the Shoot of, Prof. W. H. Lang, 872
Oxalic Acid, A New Synthesis of, C. Matignon and C. Faurholt, 335
Oxford : and the Empire, The Vice-Chancellor of Oxford University, 630 ; The Imperial Forestry Institute at, 97 ; University : conferment of honorary degrees, 29 ; approval of the nomination of Dr. H. Eltringham as Curator of the Hope Collections ; proposed extension of the departments of Physiology and Biochemistry, 736

Oyster Mortality, Prof. J. Stanley Gardiner, 82 ; Report on, G. Stubbs and others, 913
Oysters in English Oyster Beds during 1920 and 1921, An Account of Investigations into the Cause or Causes of the unusual Mortality among, Part I. : Report, Dr. J. H. Orton (assisted in Laboratory Work by Miss Edith Worsnop), 82

Pachytheca in the Buildwas Beds, Occurrence of, G. Andrew, 810
Padmā, The Age of the, B. Bhattacharyya, 372
Palæolithic Skulls from Caves in Somerset, Sir Arthur Keith, 63
Pal Empire in Bengal, The Art of the, J. C. French, 445
Panama, The Marine Fishes of, S. E. Meek and S. F. Hildebrand, 909
Pansy, Blue, The Colouring Matter of the, G. S. Currey, 73
Paper : -making : Industry, Report of H.M. Inspector on Technical Education in England for the, 951 ; Technical Education in Relation to, 951 ; Manufacture, Asphalt in, 873
Papua, Poisons and Witchcraft in, Rev. R. L. Turner, 291
Papworth Village Settlement for Tuberculosis, The, Dr. Varrier-Jones, 549
Parabola, Approximate Rectification of the, J. H. Hardcastle, 159
Paralysis, General, The Malarial Treatment of, 164 ; Prof. W. Yorke, 615
Paramo Plants of the Colombian Andes, Dr. F. W. Pennell, 624
Para-orsellinic-acids, Our Knowledge of, A. Wagenhofen, 263
Parasitism, Physiological Aspects of, Prof. V. H. Blackman, 231
Paré, Ambroise, Selections from the Works of, with Short Biography and Explanatory and Bibliographical Notes, by Dorothea Waley Singer, 46
Parker Plant for Low Temperature Carbonisation, 914
Parliamentary Representatives of Universities, 701, 771
Parus major cinereus breeding in the 24 Perghanas, S. C. Law, 371
Pasteur Institute Laboratory at Kindia, French Guinea, The, 762
Pathological and Bacteriological Laboratory Assistants' Association, Conference of the, presentation of the Woodhead medal and address to A. Norman, 443
Pauperism in the U.S., Prof. Raymond Pearl, 837
Pea Crabs, The Larvæ of the, O. W. Hyman, 63
Pearl : in a Coconut, A, E. de Ceuster, 690 ; in Oceania, The, Dr. A. C. Haddon, 909 ; Mussel, Life History of the, Prof. A. E. Boycott, 276
Pearls : Natural, A Method of distinguishing, from Culture Pearls, A. Dauvillier, 774 ; Real and Cultivated, X-ray Examination of, A. Dauvillier, 874 ; The Origin of, 868
Peat : Deposits, The Ages of, Dr. W. H. Pearsall, 829 ; Moor, Fauna of the, O. Harnisch, 765
Pechmann Dyes, etc., The Constitution of the so-called, M. T. Bogert and J. J. Ritter, 703
Pecilothermic Organisms, Variation in the Radio-sensibility of the Cellular Elements in, C. Artom, 595
Penang Hills Railway, 839
Pengelly, William, The Work of, 58
Pensions, Civil List, 135
Periodicities, Mechanical Analysis of, H. de Miffonis, 945
Permeability, Prof. W. Stiles, 784
Permian Insects, Sellards and Dunbar, and Dr. R. J. Tillyard, 730
Permo-Carboniferous System in the Hunter River Valley, The Stratigraphy of the Basal Portion of the, W. R. Brown and W. S. Dun, 919
Pernitrosocamphor and Potassium Cyanide, Reaction between, M. Passerini, 667
Perseids : August, W. F. Denning, 135 ; of 1924, The, W. F. Denning, 290
Peru, The Pre-Inca and Inca Culture of, A. L. Kroeber and W. D. Strong, 694
Pests in Glass-houses, Control of, 587
Petroleum : and its Products, Standard Methods of Testing, 639 ; Primitive Fishes and, 671 ; Production Engineering, A Textbook of, Prof. L. C. Uren, 495 ; Technologists, Institution of : awards of the, 621 ; Scholarship of the, awarded to G. Cotton, 807
Petromyzon, The Phenomenon of Contraction in Relation to Sexual Maturity and to Senescence in, G. Cotronei, 595
Pflanzen, Die Entfaltungsbewegungen, und deren teleologische Deutung. Ergänzungsband zur "Organographie der Pflanzen," Prof. K. Goebel. Zweite Auflage, 425
Pflanzenfamilien : Die natürlichen, nebst ihren Gattungen und wichtigeren Arten insbesondere den Nutzpflanzen, A. Engler und K. Prantl. Zweite Auflage, herausgegeben von A. Engler. Band 10, Hälfte I., 784
Pharmacy, Present and Future, E. White, 201
Phenological Research, International Co-operation in, J. E. Clark, I. D. Margary, and R. Marshall, 607 ; Notes on the Bioclimatic Law, Dr. A. D. Hopkins, 608
Philippine : Earthquakes, Distribution of, Rev. M. S. Masó, 482 ; Volcanoes, Active, 367
Philosophy : International Congress of, Naples, Relativity at the, Dr. T. Greenwood, 66 ; Modern, Introduction to, C. E. M. Joad, 678 ; Science and, 669 ; The Scientific Approach to, Prof. H. Wildon Carr, 146 ; Where, joins Forces with Mathematics, Prof. H. Wildon Carr, 187
Phosphorescence, Influence of Magnetic Fields on, Dr. E. Rupp, 553
Phosphorus : The Glow of, Lord Rayleigh, 612 ; The Non-luminous Oxidation of, in an Oxygen Atmosphere, Lord Rayleigh, 30
Photochemistry, First Law of, Mrs. M. C. C. Chapman, 328
Photoelectric : Cells, The Amplification of the Current of, and its Application to Precision Astronomy, R. Jouaust, 739 ; Effect with Minute Mercury Spheres, The, Dr. E. Wasser, 658
Photographic : Desensitisers, New, Pathé-Cinéma, 874 ; Development after Fixing, Lumière and Seyewetz, 102 ; Emulsions, Sedimentary Analysis of, F. F. Renwick, 292 ; Image, Latent, Study of the, L. Lumière, A. Lumière, and A. Seyewetz, 211 ; Lenses, Development of, Prof. M. von Rohr, 256 ; Plates : for the Detection of Mass Rays, Dr. F. W. Aston, 918 ; The Uniform Development of, G. M. B. Dobson and D. N. Harrison, 752
Photographie des couleurs, La, Prof. J. Thovert, 379
Photography : Certain Fundamental Problems in, Dr. T. Slater Price, 586 ; in Science, Industry, and Medicine, T. Thorne Baker, 99
Photometry, Abney Sectors in, F. E. Cady, 683
Photosynthesis, Mechanism of, J. Peklo, 446
Photo-voltaic Phenomena, R. Audubert, 702
Phthalonic Acid, The Constitution of, A. Cornillot, 335
Phylogeny as an Independent Science, 889
Physical : and Physico-chemical Problems relating to Textile Fibres, Dr. A. E. Oxley ; Dr. W. L. Balls, and others, 27 ; Science, The Recent Development of, W. C. D. Whetham. New edition, 640 ; World, Our : a Source Book of Physical Nature Study, E. R. Downing. With a chapter on Radio-Communication by F. G. Anibal, 710
Physics : Vol. I. : Mechanics, Heat and Heat Engines, W. J. R. Calvert, 344 ; A Text-Book of, including a Collection of Examples and Questions, Dr. W. Watson. Eighth edition, revised by Dr. H. Moss, 344 ; Everyday, H. E. Hadley, 820 ; for All, 710 ; Modern, A Veteran's View of, 599 ; Practical : Exercises and Problems in, with Notes on the Theory, G. N. Pingriff, 893 ; Laboratory Experiments in, to accompany the revised edition of Black and Davis' "Practical Physics," 929
Physikalisch-Technische Anstalt, Berlin, Prof. F. Paschen installed as president of the, 797
Physikalische Chemie der Zelle und der Gewebe, Prof. R. Höber. Fünfte Auflage, Hälfte 2, 678
Physiological Optics, Prof. W. Peddie, 887 ; Helmholtz's Treatise on, translated by Prof. J. P. C. Southall. Vol. I., 887

Physiology, Human : a Practical Course, C. G. Douglas and J. G. Priestley, 675 ; Practical, 675
Physiotherapy Technic : a Manual of Applied Physics, Dr. C. M. Sampson, 190
Physique et Radium, Journal de, 871
Physische Meereskunde, Prof. G. Schott. Dritte Auflage, 606
Phytopathological Service of England and Wales, The Present Position of the, J. C. F. Fryer and G. H. Pethybridge, 478
Phytophthora, Heterothallism in, C. H. Gadd, 729
Phytophthora infestans, Action of Potassium Bichromate and Copper Bichromate on the Growth of, A. and R. Sartory, 211
Phytoplankton : of the English Lakes, Mrs. W. H. Pearsall and Dr. W. H. Pearsall, 809 ; of the Lowland Waters of Great Britain : of Shropshire, Cheshire, and Staffordshire, B. M. Griffiths, 809
Pighude (Echinodermer), Dr. T. Mortensen, 747
Pigments : Paints and Varnishes, Chemistry in the Manufacture of, C. A. Klein, 491 ; Varnishes, and Building Stones, Prof. A. P. Laurie, 769
Pinacones, The Dehydration of some New, R. Locquin and L. Leers, 111
Pituitary : Body, The Histology of the, G. R. de Beer, 917 ; Extracts, The Action of, Dr. L. T. Hogben and W. Schlapp, 291
Place Names, Origins in. VI. : Life, An Ignorant Student, 410
Planet or Comet ? 655
Planetarium, The Optical, at Munich, 937
Planetary Discs, Distribution of the Radiating Power on, determined with the Interferometer, M. Maggini, 262
Planetenräumen, Die Rakete zu den, H. Oberth, 270
Planets : and Stars, Brightness of, C. Schoen, 945 ; Minor, 21, 693
Plant : Alkaloids, The, Dr. T. A. Henry. New edition, 379 ; Biology, Some Poetic Allusions to Phenomena of, Dr. W. R. G. Atkins, 158 ; Breeding : in India, Conference on, 20 ; The Economic Possibilities of, F. L. Engledow and others, 293 ; Commonwealth, The, and its Mode of Government, Sir Frederick Keeble, 13, 55 ; Disease Surveys in the British Empire, Dr. Butter and others, 207 ; Diseases : Influence of Soil Conditions on, Nowell and others, 208 ; Investigation of, Encouragement of Private Enterprise in the, Tunstall and others, 207 ; Pathology, Popular and Scientific Nomenclature in, Standardisation of, Cunningham and others, 207 ; Pigments, Studies in, Part II., J. M. Petrie, 596 ; Quarantines, 337 ; Studies, Prof. J. A. Todd, 306 ; Virus Disease, The Transmission of a New, by Insects, H. H. Storey, 245
Plantæ novæ Sinenses, H. Handel-Mazzetti, 300 ; diagnosibus brevibus descriptæ, H. Handel-Mazzetti, 263
Plants : Cultivated, Manual of : a Flora for the Identification of the most Common or Significant Species of Plants grown in the Continental United States and Canada for Food, Ornament, Utility, and General Interest, both in the Open and under Glass, Prof. L. H. Bailey, 748 ; poisonous to Live Stock, H. C. Long. New edition, 892 ; the Growth of, Effect of Artificial Light on, R. B. Harvey and others, 732 ; Vegetative Propagation of, Edinburgh Conference on the, 179
Platygaster, The Twinning and Monembryonic Development of, R. W. Leiby and C. C. Hill, 255
Plumage, Importation of, (No. 2) Order, 1922, and (No. 1) Order, 1923, alterations under the, 170
Pneumonia Increasing ? Is, E. Tomanek and E. B. Wilson, 112
Pœcilozonites, Recent and Fossil, Dr. H. A. Pilsbry, 64
Polar : Climates, Mild, The Problem of, C. E. P. Brooks, 953 ; Front, Investigations relative to the, J. W. Sandström, translated by W. W. Reed, 657
Polarised Light and Starch Content of Plants, E. Sidney Semmens, 719
Pollen Grains, Vitality of, S. Nohara, 23
Pollination, Experimental : an Outline of the Ecology of Flowers and Insects, F. E. Clements and F. L. Long, 92
Polonium : α-rays in Oxygen and Nitrogen, Ranges of, Mlle. Curie and N. Yamada, 911 ; carried down by Silver Chloride, J. Escher-Desrivières, 299 ; in Oxygen and in Nitrogen, The Distribution of the Length of the α-rays of, Mlle. Irène Curie and N. Yamada, 739 ; The Anomalous Emission of α-particles from, Dr. R. W. Lawson, 121 ; The Carrying down of, by Colloids, J. H. Brennen, 299
Polynesia, Past and Passing Peoples of, S. H. Ray, 295
Polypeptides in Oats, Jodidi, 516
Popularisation and Sensationalism, 597
Population : and Environment, Dr. S. M. Shirokogoroff, 22 ; and the Social Problem, J. Swinburne, 405 ; Growth, Laws governing, Dr. T. H. C. Stevenson, 943 ; The Growth of, and the Factors which control it, G. U. Yule, 917
Potassium : Oxalate, The Electrolysis of Solutions of, with a Tin Anode, etc., F. H. Jeffery, 182 ; -sodium Felspars : Disentangling, E. Dittler and A. Köhler, 300 ; Experiments on, E. Dittler and A. Köhler, 846
Potential Gradient and Atmospheric Pollution, Prof. Kerr Grant, 576
Potts, Howard N., Gold Medal of the Franklin Institute, W. Gaertner awarded the, 99
Power Station : Design, Developments in, E. Austin, 8 ; Efficiency Control, J. Bruce. With an appendix by R. H. Parsons, 571
Prakrit and Sanskrit Linguistics, Sir George Grierson, 587
Precipitation, Electrical, Sir Oliver Lodge, 664
Pre-Columbian Representations of the Elephant in America, Dr. H. O. Forbes, 174
Prehistoric : Egyptian Vases, The " Ship-designs " on, Dr. H. O. Forbes, 499 ; Representations of the Human Form from Malta and Gozo, Drs. Zammit and Singer, 391 ; Times, 408
Preservatives in Food, Report of Departmental Committee on, 877
Pressure Shift, Temperature Class, and Spectral Terms, Relation between, M. A. Catalán, 192
Primates, the Axis in the, Asymmetry of, Dr. Delattre, 837
Primitive : American Decorative Art, Interpretations of, Dr. H. O. Forbes, 716 ; Societies, Disintegration in, Capt. G. Pitt-Rivers, 101
Probabilités, Éléments de la théorie des, Prof. É. Borel. 3e édition, 303
Probability : Integral, An Approximation to the, Prof. H. C. Plummer, 610 ; in Theory and Practice, 303
Professional Schools and Post-graduation Courses in Great Britain and Ireland, 701
Protéines, Les, Prof. J. Lœb. Traduit de l'Anglais par H. Mouton, 928
Protozoology, Human, Profs. R. W. Hegner and W. H. Taliaferro, 308
Pseudo-Epiberberine, Buck and Perkin, 589
Psicologia sperimentale, Nuovi orizzonti della, A. Gemelli. Seconda edizione, 712
Psychical Research, 638 ; Society for, Presidential Address to the, J. G. Piddington, 324
Psychological Tests of Educable Capacity and their Possible Use in the Public System of Education, Report on, 489
Psychologists and Examiners, 489
Psychology : Applied, Prof. B. C. Ewer, 423 ; as a Science, 819 ; Some Applications of, Winifred Spielman, 423
Public : Archives, The, their Value to Scientific Research, G. Botha, 802 ; Health, The Teaching of, Dr. A. Balfour, 480
Pulpwood and Wood Pulp in North America, R. S. Kellogg, 47
Pultenæa, Revision of the Genus. Part IV., H. B. Williamson, 523
Pulverised Fuel, D. Brownlie, 65
Pumping, The Modern Theory and Practice of : a Treatise on the Application of the Reynolds-Stanton Law of Viscous Flow to Modern Pumping Problems and the Flow of Liquids through Pipes, N. Swindin, 240
Pure Science, Handbook to the Exhibition of, 134
Purposive Striving as a Fundamental Category of Psychology, Prof. W. McDougall, 231

Pygmy Flints from the Pennines, J. E. Patch, 872
Pyramid : and Prophecy, 603 ; D. Davidson, 750 ; The Reviewer, 751 ; The Great, its Divine Message : an Original Co-ordination of Historical Documents and Archæological Evidences, D. Davidson and H. Aldersmith. Vol. I., 603
Pyrus lagenarius, G. H. Stilwell and H. White, 917

Quantisation in Space and the Relative Intensities of the Components of Infra-red Absorption Bands, E. C. Kemble, 264
Quantum Theory of Radioactive Disintegration, The, Dr. A. Smekal, 327
Quartz Glass Manufacture, Dr. von Schwarz, 516
Quasi-periodic Functions, H. Bohr, 148
Queen's College, London, appeal for funds, 593
Queensland mineral resources, pamphlets on, 254

Race between a Man and a Horse, 324
Racing Eight, The : Notes on its Design and Propulsion, W. B. Coventry, 497
Radial Velocities and the Curvature of Space-time, Dr. L. Silberstein, 347
Radiation : A Biological Study of, 118 ; H. A. Colwell and Prof. S. Russ, 313 ; and Masses of Stars, Prof. H. Vogt, 480 ; of Varying Wave-length, The Relative Absorbing Powers of the *L*-levels for, H. W. B. Skinner, 75 ; Recorder, A Comparison of Three Different Types of, W. B. Haines, 210 ; Therapy, Rationale of, 515
Radiations in the Region between the Ultra-violet Rays and the X-rays, A New Method of Production of, G. Reboul and Bodin, 211
Radioactive Substance, Estimation of, by γ-rays, Dr. W. Bothe, 65
Radioactivity : Feeble, The Measurement of, Dr. G. Hoffmann, 483 ; of the Granites from Guérat, near Bagnoles-de-l'Orne. Study of Emilium, P. Loisel, 594 ; of the Rocks, The (Hugo Müller Lecture), Prof. J. Joly, 160
Radio Communication : and Research in Great Britain, 520 ; with the Antipodes, 725 ; Senatore G. Marconi, 939
Radio : Fog Signals for the Protection of Navigation ; Recent Progress, G. R. Putnam, 263 ; Telegraphy, The Beam System of, Senatore Marconi, 359 ; Transmission of Photographs, 834
Radiology, British Institute of, Prof. S. Russ, 770
Radium : Bromide, Small Variations in the Heat Disengaged by Various Specimens of, J. H. Le Bel, 299 ; -C, Disintegration of, Sir Ernest Rutherford and Dr. J. Chadwick, 483 ; The Maximum Range of the Particles discharged from, D. Pettersson, 263 ; The Preparation of Line Sources of, Dr. G. H. Henderson, 503 ; Emanation, The Decay Constant of, L. Bastings, 918 ; -*E*, The Number of β-particles from, K. G. Emeleus, 76 ; The Number of α-particles emitted by, V. F. Hess and Dr. R. W. Lawson, 205 ; X-rays and the Living Cell : with Physical Introduction, H. A. Colwell and Prof. S. Russ. Second edition, 118
Radon, The Radioactive Constant of, Mlle. I. Curie and Mlle. C. Chamié, 205
Raffles Museum, and Library, Report of the, Major J. C. Moulton, 254 ; C. B. Kloss, 621
Rafflesia Arnoldi R. Br. and *Brugmansia Lowii* Becc., Dr. A. B. Rendle, 953
Rain, Heavy, in Somerset, 365
Rainbows, the Light of, Polarisation of, G. B. Deodhar, 860
Rainfall : and Sunspots, Lake Level in Relation to, Dr. F. Dixey, 659 ; in Australia, 255 ; for the British Isles, Monthly Normals of, 619 ; Frequent, over the British Isles, C. E. P. Brooks, 479 ; The Periodicity of, G. W. Cox, 631
Ramsay Memorial : Fellowships : award of, to S. W. Saunders, A. Robertson, and K. J. Pedersen, 181 ; awards of, 771 ; Laboratory, University College, London, The opening of the, 805
Rana temporaria, The Motor Nerve-endings of the Limb Muscles of the Frog, and of the Muscles of the Pectoral Fin of the Dog-fish (*Squalus acanthias*), P. D. F. Murray, 595
Rarer Elements, The, 375
Rat Menace, The : its Real Significance and how it may be minimised, T. M. Hovell, 727
Rayleigh : Lord, The Life of, Sir J. J. Thomson, 814 ; Third Baron, John William Strutt, O.M., F.R.S., sometime president of the Royal Society and chancellor of the University of Cambridge, R. J. Strutt, Fourth Baron Rayleigh, 814
Reale Accademia Nazionale dei Lincei, Sir William Pope elected a foreign member of the, 99 ; Prof. F. Soddy elected a foreign member of the, 366
Recknagel's Disc, The Use of, as an Indicator of Velocity and Direction, A. Foch, 667
Recording Balance, An Automatic and Continuous, J. R. H. Coutts, E. M. Crowther, B. A. Keen, and S. Odén, 72
Red Algæ, Development and Liberation of Spermatia in some Undescribed Cases among the, Miss Violet M. Grubb, 953
Reflective Thinking, An Introduction to, L. Bauermeyer and others, 785
Refractive Index, The Influence of Atomic Arrangement on, Prof. W. L. Bragg, 73
Refrigeration, The Fourth International Congress of, Dr. E. Griffiths, 257
Rejuvenation, Dr. F. A. E. Crew, 530 ; and the Prolongation of Human Efficiency : Experiences with the Steinach-operation on Man and Animals, Dr. P. Kammerer, 530
Relatività, Teoria della : saggio di una esposizione secondo il senso fisico, Prof. P. Straneo, 565
Relativitätstheorie : Darstellung der, im Dreidimensionalen Lobatschefskijschen Raume, Prof. V. Varićak, 820 ; Einsteins, Die spezielle, und die Logik, Dr. J. N. Tummers, 713
Relativité : Bibliographie de la, M. Lecat and Mme. M. Lecat-Pierlot, 8 ; La, Théorie quantique des spectres, Dr. N. R. Campbell. Traduit de l'anglais par A. Corvisy, 565
Relativity, 565 ; A Philosopher on, Sir Oliver Lodge, 318 ; at the International Congress of Philosophy, Naples, Dr. T. Greenwood, 66 ; for Physics Students, Prof. G. B. Jeffery, 820 ; Mathematics of, Prof. S. Brodetsky, 339 ; Optical Records and, Prof. C. Lloyd Morgan, 577, 681 ; Prof. H. Wildon Carr, 681 ; The Mathematical Theory of, Prof. A. S. Eddington. New edition, 782 ; The Theory of, Studies and Contributions, A. Henderson, A. W. Hobbs, and J. W. Lasley, Jr., 565 ; The Common Sense of, Dr. P. R. Heyl, 820
Religion : Biology and, Prof. J. S. Haldane, 468 ; Science and, 373
Religions, Living, 561 ; a Plea for the Larger Modernism, V. Branford, 562
Rennin, The Destruction of, by Agitation : a Case of Catalysis at an Air-liquid Interface, Dr. E. K. Rideal and C. G. L. Wolf, 31
Rensselaer Polytechnic Institute, Troy, The, and some of its Services to Science, Prof. R. P. Baker, 808
Research, Dr. W. R. Ormandy, 652 ; Productive, The State and, J. W. Williamson, 705 ; Station, The Work of a, W. B. Hardy, 257 ; the Mother of Industry, Dr. A. D. Little, 288
Resins, The Vegetation of, C. Cappelletti, 631
Resonance Radiation : the Polarisation of, Effect of the Magnetic Field on, F. Rasetti, 631 ; in Magnetic Fields, Polarisation of, A. Ellett, 931

REVIEWS AND OUR BOOKSHELF.

Agriculture, Forestry, and Horticulture :

Ainsworth-Davis (Prof. J. R.), Crops and Fruits (The Resources of the Empire Series. Vol. I., Part I.), 526 ; Meat, Fish, and Dairy Produce (Vol. I., Part II.), 526
Bailey (Prof. L. H.), Manual of Cultivated Plants : a Flora for the Identification of the most Common or

Significant Species of Plants grown in the Continental United States and Canada for Food, Ornament, Utility, and General Interest, both in the Open and under Glass, 748
Baker (R. T.), and H. G. Smith, Wood-fibres of some Australian Timbers: Investigated in Reference to their Prospective Value for Paper-pulp Production, 190
Bruttini (Prof. A.), Uses of Waste Materials: the Collection of Waste Materials and their Uses for Human and Animal Food, in Fertilisers, and in Certain Industries, 1914–1922, 460
Copeland (Prof. E. B.), Rice, 455
Evergreens, The Cultivated: a Handbook of the Coniferous and most important Broad-leaved Evergreens planted for Ornament in the United States and Canada. Edited by Prof. L. H. Bailey, 240
Gilbert-Carter (H.), Descriptive Labels for Botanic Gardens, 748
Harding (R.), Cotton in Australia: the Possibilities and the Limitations of Australia as a Cotton-growing Country, 819
Hutcheson (Prof. T. B.), and Prof. T. K. Wolfe, The Production of Field Crops: a Textbook of Agronomy, 817
Kellogg (R. S.), Pulpwood and Wood Pulp in North America, 47
Ladd (Prof. C. E.), Dairy Farming Projects, 822
Long (H. C.), Plants Poisonous to Live Stock. New edition, 892
Maclaren (W. A.), Rubber, Tea, and Cacao: with Special Sections on Coffee, Spices, and Tobacco (The Resources of the Empire Series. Vol. V.), 526
Malden (W. J.), Grassland Farming, Pastures and Leys, 817
Millais (J. G.), Rhododendrons and the various Hybrids. Second Series, 636
Timber and Timber Products, including Paper Making Materials. Edited by S. J. Duly (The Resources of the Empire Series. Vol. II.), 526
Ward (J. S. M.), Textile Fibres and Yarns (The Resources of the Empire Series. Vol. III.), 526

Anthropology and Archæology:

Ajisafe (A. K.), The Laws and Customs of the Yoruba People, 745
Blackman (Dr. A. M.), The Rock Tombs of Meir. Part 4, 461
Boyle (Mary E.), Man before History: a Short Account of Prehistoric Times, 410
Crawford (O. G. S.), Air Survey and Archæology (Ordnance Survey Professional Papers. New Series. No. 7), 570
Crookshank (Dr. F. G.), The Mongol in our Midst: a Study of Man and his Three Faces, 605
Davidson (D.), and H. Aldersmith, The Great Pyramid, its Divine Message: an Original Co-ordination of Historical Documents and Archæological Evidences. Vol. I.: Pyramid Records, 603
Dundas (Hon. Charles), Kilimanjaro and its People: a History of the Wachagga, their Laws, Customs, and Legends, together with some Account of the Highest Mountain in Africa, 711
Fessenden (Prof. R. A.), The Deluged Civilization of the Caucasus Isthmus, 892
Fox (Dr. C.), The Archæology of the Cambridge Region: a Topographical Study of the Bronze, Early Iron, Roman, and Anglo-Saxon Ages, with an Introductory Note on the Neolithic Age, 494
Frazer (Lady), Leaves from the Golden Bough, 854
Goessler (Prof. P.), L'Homme préhistorique dans l'Europe centrale: Primeval Man in Central Europe, 410
Grinnell (G. B.), The Cheyenne Indians: their History and Ways of Life. 2 vols., 188
Kummer (F. A.), The First Days of Knowledge: as narrated quite simply for Young Readers (The Earth's Story. Vol. II.), 533
Lodge (Sir Oliver), Making of Man: a Study in Evolution, 408
Lothrop (Dr. S. K.), Tulum: an Archæological Study of the East Coast of Yucatan, 893
Milne (Mrs. Leslie), The Home of an Eastern Clan: a Study of the Palaungs of the Shan States, 929
Murray (Miss M. A.), Excavations in Malta. Part I., with a Chapter by G. C. Thompson, 462
Norden (H.), White and Black in East Africa: a Record of Travel and Observation in two African Crown Colonies, 745
Origins in Place Names, An Ignorant Student. VI.: Life, 410
Perry (W. J.), The Growth of Civilization, 272
Roscoe (Rev. Canon J.), The Bagesu and other Tribes of the Uganda Protectorate: the Third Part of the Report of the Mackie Ethnological Expedition to Central Africa, 745
Smith (Prof. G. Elliot), Elephants and Ethnologists, 923; The Evolution of Man: Essays, 410
Sollas (Prof. W. J.), Ancient Hunters and their Modern Representatives. New edition, 408
Spence (L.), The Problem of Atlantis, 409
Stone (E. H.), The Stones of Stonehenge: a Full Description of the Structure and of its Outworks, 634
Talbot (P. A.), Life in Southern Nigeria: the Magic, Beliefs, and Customs of the Ibibio Tribe, 43

Biology:

Atwood (W. G.), A. A. Johnson, and others, Marine Structures: their Deterioration and Preservation. Report of the Committee on Marine Piling Investigations of the Division of Engineering and Industrial Research of the National Research Council, 744
Baker (E. C. Stuart), Birds. Vol. 2. Second edition (The Fauna of British India, including Ceylon and Burma), 427
de Beer (G. R.), Growth, 709
Bennett (F. T.), Outlines of Fungi and Plant Diseases: for Students and Practitioners of Agriculture and Horticulture, 306
Bentham (G.), revised by Sir J. D. Hooker. Seventh edition, revised by Dr. A. B. Rendle. Handbook of the British Flora: a Description of the Flowering Plants and Ferns Indigenous to, or Naturalised in, the British Isles; for the Use of Beginners and Amateurs, 379
Biologischen Arbeitsmethoden, Handbuch der, Ed. Prof. E. Abderhalden. Abt. XI. Teil 1, Heft 7 (Schluss), Lief. 134, 747

Watson (Prof. F. R.), Acoustics of Buildings : including Acoustics of Auditoriums and Sound-proofing of Rooms, 85
Watson (Dr. W.), A Text-Book of Physics : including a Collection of Examples and Questions. Eighth edition, revised by Dr. H. Moss, 344
Whetham (W. C. D.) : Matter and Change : an Introduction to Physical and Chemical Science, 710 ; The Recent Development of Physical Science. New edition, 640
Whittaker (Prof. E. T.), and G. Robinson, The Calculus of Observations : a Treatise on Numerical Mathematics, 377

Medical Science :

Barker (J. Ellis), Cancer : How it is Caused, How it can be Prevented, 496
Bond (C. J.), The Leucocyte in Health and Disease : being an Enquiry into certain Phases of Leucocytic Activity, 784
Cancer Research at the Middlesex Hospital, 1900–1924 : Retrospect and Prospect. Edited by W. S. Handley, 533
Colwell (H. A.), and Prof. S. Russ, Radium, X-rays and the Living Cell : with Physical Introduction. Second edition, 118
Douglas (C. G.), and J. G. Priestley, Human Physiology : a Practical Course, 675
Evans (W. H.), The Diseases of the Breast, 120
Harger (Dr. J.), Cancer : its Causation, Prevention and Cure, 855
Keynes (G.), A Bibliography of Sir Thomas Browne, Kt., M.D., 678
Macpherson (Maj.-Gen. Sir W. G.) : History of the Great War, based on Official Documents. Medical Services : General History. Vol. 3 : Medical Services during the Operations on the Western Front in 1916, 1917, and 1918 ; in Italy ; and in Egypt and Palestine, 154 ; and Maj. T. J. Mitchell : History of the Great War : Based on Official Documents. Medical Services : General History. Vol. 4 : Medical Services during the Operations on the Gallipoli Peninsula ; in Macedonia ; in Mesopotamia and North-west Persia ; in East Africa ; in the Aden Protectorate, and in North Russia. Ambulance Transport during the War, 678
Rivers (Dr. W. H. R.), Medicine, Magic and Religion : the FitzPatrick Lectures delivered before the Royal College of Physicians of London in 1915 and 1916, 563
Sampson (Dr. C. M.), Physiotherapy Technic : a Manual of Applied Physics, 190
Savage (Dr. W. G.), Canned Foods in Relation to Health, 120
Singer (Dorothea Waley), Selections from the Works of Ambroise Paré. With Short Biography and Explanatory and Bibliographical Notes, 46
Stopes (Dr. Marie Carmichael), Contraception (Birth Control), its Theory, History, and Practice : a Manual for the Medical and Legal Professions, 601
Thompson (R. Campbell), Assyrian Medical Texts : from the Originals in the British Museum, 48
Wilkinson (G.), and Dr. A. A. Gray, The Mechanism of the Cochlea : a Restatement of the Resonance Theory of Hearing, 493
Zinsser (Prof. H.), Infection and Resistance : an Exposition of the Biological Phenomena underlying the Occurrence of Infection and the Recovery of the Animal Body from Infectious Disease ; with a Consideration of the Principles underlying Specific Diagnosis and Therapeutic Measures. New edition, 677

Metallurgy :

Blum (W.), and G. B. Hogaboom, Principles of Electroplating and Electroforming (Electrotyping), 272
Dean (R. S.), Theoretical Metallurgy, 892
Fluxes and Slags in Metal Melting and Working : a General Discussion held by the Faraday Society and the Institute of Metals, with the Co-operation of the British Non-Ferrous Metals Research Association and the Institute of British Foundrymen, April 1924, 892
Harbord (F. W.), and J. W. Hall, The Metallurgy of Steel. Seventh edition. Vol. 1 : Metallurgy, F. W. Harbord ; 2 : Mechanical Treatment, J. W. Hall, 235
Metals, Institute of, Journal of the, Vol. XXXI. Edited by G. Shaw Scott, 640
Osann (Prof. B.), Lehrbuch der Eisenhüttenkunde : verfasst für den Unterricht, den Betrieb und das Entwerfen von Eisenhüttenanlagen. Zweite Auflage. Erster Band, 235
Sisco (F. T.), The Manufacture of Electric Steel, 150

Meteorology :

British Meteorological and Magnetic Year Book, 1915. Part 5 : Réseau Mondial, 1915. Monthly and Annual Summaries of Pressure, Temperature, and Precipitation at Land Stations, generally Two for each Ten-degree Square of Latitude and Longitude, 747
Hellpach (Prof. W.), Die geopsychischen Erscheinungen : Wetter und Klima, Boden und Landschaft in ihrem Einfluss auf das Seelenleben. Dritte Auflage, 44
Kähler (Dr. K.), Die Elektrizität der Gewitter, 890
Köppen (Prof. W.), Die Klimate der Erde : Grundriss der Klimakunde, 44
Simpson (Dr. G. C.), British Antarctic Expedition, 1910–1913. Meteorology. Vol. 3 : Tables, 853

Miscellaneous :

Avebury, Lord, The Life-work of (Sir John Lubbock), 1834–1913. Edited by the Hon. Mrs. Adrian Grant Duff, 239
Bird (W. H.), Collective Index of the Journal of the Institute of Brewing, 1911 to 1923, 677
Branford (V.), Living Religions : a Plea for the Larger Modernism, 562
Cambridge Readings in the Literature of Science : being Extracts from the Writings of Men of Science to illustrate the Development of Scientific Thought. Arranged by W. C. D. Whetham and Margaret Dampier Whetham, 404
Coal and Power : the Report of an Enquiry presided over by the Rt. Hon. D. Lloyd George, 265
Elderton (W. Palin), and H. J. P. Oakley, The Mortality of Annuitants, 1900–1920 : Investigation and Tables, 855
Empire Series, The Resources of the, Vol. I. Parts I. and II. ; Vol. II. ; Vol. III. ; Vol. V. ; Vol. VI., 526
Exhibition of Pure Science, Handbook to the [British Empire Exhibition]. Arranged by the Royal Society, 462

Heitland (W. E.), Behind and Before : Two Essays on the Relation of History, Politics and Eugenist Warnings, 569
Hering (Prof. D. W.), Foibles and Fallacies of Science : an Account of Celebrated Scientific Vagaries, 458
Isis : The International Review devoted to the History of Science and Civilisation. Edited by Dr. G. Sarton, 404
Perret (F. A.), The Vesuvius Eruption of 1906 : a Study of a Volcanic Cycle, 851
Science, The Advancement of, 1924, 185
Science and Labour : being the Principal Addresses at the Conference on Science and Labour held in London on 30th and 31st May 1924. Edited by T. Ll. Humberstone, 849
Scientific and Learned Societies of Great Britain and Ireland, The Year-Book of the. Fortieth Annual Issue, 119
Smith (Prof. J. A.), The Nature of Art : an Open Letter to the Professor of Poetry in the University of Oxford, 569
Subject Index to Periodicals, The, 1917–1919. L : List of Periodicals Indexed and Author Index, 346
Venn (Dr. J.), and J. A. Venn, Alumni Cantabrigienses : a Biographical List of all known Students, Graduates, and Holders of Office at the University of Cambridge, from the Earliest Times to 1900. Part I. (in 4 vols.). From the Earliest Times to 1751. Vol. 3, 459

Philosophy and Psychology :

Bailey (C. W.), and a Chapter on Theory and Practice by B. Darwin, The Brain and Golf : Some Hints for Golfers from Modern Mental Science, 271
Buermeyer (L.), and others, An Introduction to Reflective Thinking, 785
Burthogge, Richard, The Philosophical Writings of. Edited, etc., by Margaret W. Landes, 822
Cassirer (Prof. E.), translated by Drs. W. C. and Marie C. Swabey. Substance and Function and Einstein's Theory of Relativity, 187
Dunraven (Earl of), Experiences in Spiritualism with D. D. Home, 638
Edgell (Dr. Beatrice), Theories of Memory, 893
Elsbach (Dr. A. C.), Kant und Einstein : Untersuchungen über das Verhältnis der modernen Erkenntnistheorie zur Relativitätstheorie, 748
Ewer (Prof. B. C.), Applied Psychology, 423
Ewing (Dr. A. C.), Kant's Treatment of Causality, 569
Forel (Prof. A.), La Monde social des fourmis, comparé à celui de l'homme, 79
Gemelli (A.), Nuovi orizzonti della psicologia sperimentale. Seconda edizione, 712
Harnack (A. von), Immanuel Kant, 1724–1924 : Gedächtnisrede zur Einweihung des Grabmals im Auftrag der Albertus-Universität und der Stadt Königsberg in Preussen am 21 April 1924 im Dom zu Königsberg gehalten, 748
Joad (C. E. M.), Introduction to Modern Philosophy, 678
Jung (É.), Le Principe constitutif de la nature organique, 822
Kohs (Prof. S. C.), Intelligence Measurement : a Psychological and Statistical Study based upon the Block-design Tests, 423
Kries (Prof. J. von), Immanuel Kant und seine Bedeutung für die Naturforschung der Gegenwart, 748
Locke (John), An Essay concerning Human Understanding. Abridged and edited by Prof. A. S. Pringle-Pattison, 462
McCall (Prof. W. A.), How to Experiment in Education, 423
McDowall (Rev. S. A.), Evolution, Knowledge and Revelation : being the Hulsean Lectures delivered before the University of Cambridge, 1923–24, 606
Radhakrishnan (Prof. S.), Indian Philosophy. Vol. 1, 714
Roth (Dr. L.), Spinoza, Descartes, and Maimonides, 785
Schiller (Dr. F. C. S.), Problems of Belief, 856
Swinburne (J.), Population and the Social Problem, 405
Thorndike (Prof. E. L.), M. V. Cobb, J. S. Orleans, P. M. Symonds, E. Wald, and E. Woodyard, The Psychology of Algebra, 423
Thurstone (Prof. L. L.), The Nature of Intelligence, 819
Vaihinger (Prof. H.), translated by C. K. Ogden, The Philosophy of " As if " : a System of the Theoretical, Practical, and Religious Fictions of Mankind, 714

Technology :

Beck (C.), The Microscope. Part II. An Advanced Handbook : a Sequel to " The Microscope, a Simple Handbook," 571
Bryson (T.), Theory and Practice of Mine Ventilation : a Text-book for Students and a Book of Reference for Managers and Under-managers, 7
Hetherington (A. L.), The Early Ceramic Wares of China. Popular and abridged edition, 342
Matthews (Dr. J. M.), The Textile Fibers : their Physical, Microscopical, and Chemical Properties. New edition, 421
Petroleum, Standard Methods of Testing, and its Products, 639
Rickard (T. A.), Technical Writing. New edition, 640
Snow (Dr. E. C.), Leather, Hides, Skins, and Tanning Materials. (The Resources of the Empire Series. Vol. VI.), 526

Rhodes Scholarships, Annual Statement for 1923–1924, 880
Rhododendrons, W. J. Bean, 636 ; and the various Hybrids, J. G. Millais. Second series, 636
Rice, Prof. E. B. Copeland, 455
River : -deposits of the Low Valley of the Warwickshire Avon, Miss M. E. Tomlinson, with an appendix by A. S. Kennard and B. B. Woodward, 145 ; Pollution and Fisheries, 885
Rivers Memorial Medal of the Royal Anthropological Institute, The, awarded to Dr. A. C. Haddon, 835
Road-books and Itineraries of Great Britain, The, 1570 to 1850 : a Catalogue with an Introduction and a Bibliography, Sir Herbert George Fordham, 272
Rock : Salt, The Plasticity of, in Water, W. Ewald and M. Polanyi, 766 ; Tombs of Meir, The, Dr. A. M. Blackman. Part 4, 461
Rockefeller Foundation, Review of the, for 1923, G. E. Vincent, 99
Rockets : and High-altitude Research, Prof. R. H. Goddard, 574 ; to reach Planetary Space, 270
Rocks, The Radioactivity of the (Hugo Müller Lecture), Prof. J. Joly, 160
Roman Britain, Map of, 513
Röntgen Society, the Röntgen award to be made to L. H. Clark, 762
Röntgenstrahlen, Spektroscopie der, Prof. M. Siegbahn, 237
Rose Quartz, E. F. Holden, 695
Rotatory Dispersion, Lowry and Richards, 553
Rotifera, Contributions to the Biology of the. I. : The Males of the Rotifera, C. Wesenberg-Lund, 568
Round : Barrows and the Stupa, A. M. Hocart, 391 ; Liquid Columns, The Influence of the Degree of Instability on the Phenomena of, R. A. Castleman, Jun., 857
Royal : (Dick) Veterinary College, Institution of a Centenary Post-graduate Fellowship at the, 879 ; Engineers, The Work of the, in the European War, 1914–1919. Work under the Director of Works (France). 3 Parts, 425 ; Institution, Profs. T. Lyman and G. N. Lewis elected honorary members of the, 834 ; Photographic Society's Annual Exhibition, The, 449 ; Physical Society of Edinburgh, election of officers and council, 835 ; Scholarships and Free Studentships (Science), 1924, awards of, 808 ; Society : The Election of Kelvin, Stokes and Huxley, 19 ; Anniversary Meeting of the, President's Address and presentation of medals, 840 ; donation to, by Mrs. Tyndall, 724 ; Early Science at the, 30, 72, 108, 145, 181, 209, 261, 298, 335, 371, 395, 451, 487, 522, 558, 594, 630, 666, 702, 737, 772, 808, 844, 880, 916, 953 ; medallists of the, 724 ; officers and council of the, 724 ; of Arts, award of silver medals, 62 ; of

Edinburgh, election of officers and councillors, 692; the Prince of Wales elected an honorary fellow of the, 906; of Western Australia, award of gold medal to Dr. W. J. Hancock, 365; Technical College, Glasgow, Dr. A. L. Mellanby appointed professor of mechanics and mechanical engineering; Dr. W. Kerr appointed associate professor, 71; Swedish Academy of Science, Sir Napier Shaw elected a foreign member of the, 61
Ruppia and its Environmental Factors, W. A. Setchell, 264
Russia, The Natural Resources of, 68
Russia's Contribution to Chemistry, Some Aspects of, Prof. W. P. Wynne, 662
Rydberg-Ritz Equation, The Constants of the, J. H. Jones and J. C. Boyce, 773

St. Andrews University: resignation of Prof. A. E. Taylor; D. Morrison invited to the chair of moral philosophy; Dr. G. McOwan appointed lecturer in organic chemistry in the United College; resignation of J. Stirling, 144; award of an industrial bursary to F. G. Forbes, 180; appointments in, 593; A. M. Adamson appointed assistant in the department of zoology, 736
St. George Expedition to the Pacific, The, J. Hornell, 681
St. Kieran's Cave, Excavation of, 287
Salt Hydrates, certain, Discontinuity in the Dehydration of, E. M. Crowther and J. R. H. Coutts, 74
Salters' Institute of Industrial Chemistry, awards of the, 443
Salts: Solid, The Conductivity of, at High Temperatures, P. Vaillant, 594; with Multivalent Cations, The Action of, on Colloidal Solutions of Gold and Gum Benzoin, W. O. Kermack and C. I. B. Voge, 954
Samoa, Meteorology at, 766
Sandstone Block, Some Properties of a, after Use in a Glass Furnace, H. S. Houldsworth, 955
Santonin, Constitution of, A. Angeli, 631
Sap: in Trees, Flow of, Prof. A. S. Eve, 827; The Ascent of, and Transport of Food Materials in Trees, Prof. H. H. Dixon and others, 518
Saturation in the Soil of Sulphuric Acid utilised for the Destruction of Weeds, C. Brioux, 211
Saturn, The Polarisation of, M. Lyot, 845
Saturn's Ring, The Possible Ellipticity of, G. R. Goldsbrough, 74
Scandium Lines, The Magnetic Resolution of the, S. Goudsmit and Prof. P. Zeeman, 432
Scholarships and Promotion, Tests for, Dr. C. Burt and others, 556
School Nature Study: anniversary issue, 796; Union, The, 796
Science: and Labour, Prof. H. Levy, 849; being the principal addresses at the Conference on Science and Labour held in London on 30th and 31st May 1924. Edited by T. Ll. Humberstone, 849; Major A. G. Church, 89; and Folly, 458; and Life, 185; and Literature, 399; and Philosophy, 669; and Religion, 373; and the British Empire, 526; Exhibitions, Popular, 633; A. S., 683; Foibles and Fallacies of, an Account of Celebrated Scientific Vagaries, Prof. D. W. Hering, 458; Forthcoming Books of, 413; in South Africa, Prof. H. B. Fantham, 802; Museum: Report of the, for 1921 and 1922, 61; Exhibition of Kelvin and other Instruments at the, 97; Extension of the, 725; The Exhibition of Stationary Engines and Locomotives in the, 870; Social, 405; The Advancement of, 1924, 185; The Church and Disease, 741; The New Philosophy, Prof. J. Graham Kerr, 669
Scientific: and Industrial Research, Report of the Committee of the Privy Council for, 1923–24, 705; and Learned Societies of Great Britain and Ireland, The Year Book of the, Fortieth Annual Issue, 119; and Technical Books, Recent: July 26, Suppt. v.; August 30, Suppt. v.; September 27, Suppt. v.; October 25, Suppt. v.; November 29, Suppt. iii.; December 27, Suppt. iii.; Approach to Religion, Conference on the, 364; Development, Studies of, 404; Periodicals, World List of, F. W. Clifford, 401; Thought, The History of, Dr. W. C. D. Whetham, 397; Workers and Parliament and State Departments, 199
"Scientist," The Word, or its Substitute, Dr. N. R. Campbell, 788; Sir E. Ray Lankester; Sir Clifford Allbutt, 823; H. W. Fowler; J. H. Fowler; Prof. D'Arcy W. Thompson; Prof. W. J. Sedgefield; Sir Oliver Lodge; Prof. R. W. Chambers; Sir Israel Gollancz, 824; Prof. H. Wildon Carr, 825; Prof. H. Dingle; Sir R. A. S. Paget, 897; A Chemist, 898
Scilly Isles, Fog at the, E. G. Bilham, 838
Scintillations, The Measurement of the Relative Brilliancy of, Elisabeth Kara-Michailova and H. Pettersson, 263
Scorpion Spermateleosis, The, Prof. J. B. Gatenby, 380
Scorpions: in South Africa, The Distribution of, J. Hewitt, 336; The Gametogenesis of, Cell Inclusions in, Vishwa Nath, 52
Scotoscope, The, C. E. Benham, 11
Scottish: Anthropometry, Prof. R. W. Reid and colleagues, 551; Cattle Breeding Conference, The, Dr. F. A. E. Crew, 206
Sea: -urchin, Eggs of the, Potentiometric Measurements of the P_H of the Substance of the, P. Vlès, P. Reiss, and E. Vellinger, 371; Waves, A New Method of Investigating, Prof. W. Shoulejkin, 498
Seasonal Changes: in Shell-fish, 555; in the Water and Heleoplankton of Fresh-water Ponds, Dr. W. R. G. Atkins and G. T. Harris, 775
Seaweed, Utilisation of, 172
Secotium, A Critical Revision of the Australian and New Zealand Species of the Genus, G. H. Cunningham, 212
Seeds, Germination of, exposed to Low Temperatures, H. F. Roberts, 393
Seessel, Theresa, research fellowship, a, awarded to Dr. M. C. Rayner, 558
Seismic Waves, The Propagation of, in the Neighbourhood of the Origin, Maurain and others, 211
Seismological Research in America, 548
Selective Fertilisation among the Gametes from the same Individuals, D. F. Jones, 263
Selenides, The Preparation of, from Selenium Hydride and Metallic Salt Solutions, K. Atynski, 263
Selenium: Cells and X-rays of various Wave-lengths, Dr. H. Küstner, 800; Photometer, A, F. C. Toy, 146
Selsey Bill, Weather at, E. Heron-Allen, 172
Sensationalism, Popularisation and, 597
Sensitiveness, The Effect of Oxidisers on, and on the Developable Image, S. E. Sheppard, E. P. Wightman, and A. P. H. Trivelli, 696
Severn, River, Inquiry into the Feasibility of Using the Tidal Power of the, for the Production of Electrical Power, 323
Sex: Determination, F. W. R. Brambell, 804; Glands: The Internal Secretions of the: the Problem of the "Puberty Gland," Prof. A. Lipschütz, 779; in Mushrooms and Toadstools, Experiments of, Prof. A. H. R. Buller, 826
"Shear" in Geometry, The Use of, A. Mallock, 9
Sheffield University: Dr. G. A. Clark appointed a lecturer in physiology, 106; E. F. Baxter an assistant lecturer in mathematics, 107; gift by Lord Bearsted, 209; J. G. A. Skerl appointed to take charge of an investigation on moulding sands, 450; appointments in, 593
Shell-fish, Seasonal Changes in, 555
Shipbuilding, Engineering and, J. H. Hume; T. Westgarth, 664
Shipworms in Bermuda, New Species of, W. F. Clapp, 204
Short Cist Burial in Kincardineshire, Prof. R. W. Reid and Rev. J. R. Fraser, 326
Siam, W. A. Graham. New edition. In 2 vols., 929
Silent Highways of the Jungle: being the Adventures of an Explorer in the Andes and along the Upper Reaches of the Amazon, G. M. Dyott. Second edition, 190
Silica, Fused Transparent, The Phosphorescence of, Dr. W. E. Curtis, 146
Silkworm Cocoons, The Stifling of, G. Bertrand, 481
Silver, Halides of, E. J. Hartung, 911
Silviculture, Relation of Forest Pathology to, Dr. A. W. Borthwick and others, 293
Sintered Glass Filters, Moser and Maxymowicz, 589

Size: Are the various Parts of the Body Genetically Independent in? W. E. Castle, 112; Inheritance, Nature of, K. Sax, 263; of the various Parts of the Body, The Partial Genetic Independence in, F. B. Sumner, 112
Skeletal Muscle, Influence of Initial Tension upon the Magnitude and Duration of the Mechanical Response in, J. F. Fulton, 72
Sklodowskite, A New Radioactive Mineral, A. Schoep, 396
Slug, The Large Black, at Honolulu, Prof. T. D. A. Cockerell, 502
Smallpox and Vaccination, Dr. J. J. Heagerty, 907
Smithsonian Mathematical Formulæ and Tables of Elliptic Functions, Prof. E. P. Adams and Col. R. L. Hippisley, 85
Smoke: its Cause, Nature, Effects and Methods of Prevention, Prof. J. B. Cohen, 796
Snakes from the State Museum of National History at Vienna, New or Little Known, F. Werner, 184
Soap Solutions and X-rays, Liquid Crystals, Prof. J. W. McBain, 49
Society: The Biological Foundations of, Prof. A. Dendy, 405; What is a? Judge Dowdall, 809
Sociology, Biology and, C. W. Soal, 273; Dr. B. Malinowski, 274
Sodium: Chloride in the Blood of some Marine Invertebrates, The Amount of, M. Duval, 703; Sulphate Decahydrate, Cryoscopy in, E. E. Turner and W. H. Patterson, 182; Tungstates, Dr. E. F. Smith, 483
Soil: Science, International Conference on, Dr. B. A. Keen; Prof. J. G. Lipman elected president, 25; Fauna of a Permanent Pasture, The, J. L. McWhinney, 110; Fertility, A New View of, Prof. W. F. Gericke, 657; The Microscopic Study of the, S. Winogradsky, 396
Solar: Apex and Velocity, B. Fessenkoff and C. Ogrodnikoff, 390; Eclipse, The Total, of January 24, 1925, 550; Physics at Cambridge, 480; Spectrograph for the Poulkovo Observatory, 325
Solid Solutions, Super-saturated, R. H. Greaves, 882
Solidified Gases, The Light emitted from, and its Relation to Cosmic Phenomena, Prof. L. Vegard, 357
Solubility: Prof. J. H. Hildebrand, 637; The Origin of, 637
Sophora tetraptera, Young and Adult Stages of, Miss V. Hay, 953
Sound: Records, Analytical, Dr. E. E. Fournier d'Albe, 537; Spectrum of an Explosion, The Wave-length of Maximum Energy of the, A. Dufour, 739; The Analysis of, by the Cochlea, Prof. H. E. Roaf, 493
South: Africa, The Contribution of, to the Principles of Geology, Dr. A. L. du Toit, 802; African: Life Table based on the European Male Population Census, A, C. W. Kops, 262; Association, Meeting of the, at Cape Town, 802; General J. C. Smuts elected president of the meeting at Oudtshorn, 804; Museum: Report of the, 1923, Dr. Perinquey, 621; E. L. Gill appointed director of the, 834; Sheep, A New Trichostrongylus from, H. O. Monnig, 336; Spiders, R. F. Lawrence, 212
South American Non-marine Mollusca, Dr. H. A. Pilsbry, 291
South Australia: Geology of, Sir Douglas Mawson, 946; Well-waters of, R. L. Jack, 910
South-eastern Australia, The Geological History of, with special reference to the Carboniferous and Permian Periods, C. A. Sussmilch, 69
South Uist and Eriskay, Dr. T. J. Jehu and R. M. Craig, 919
South-west Monsoon, Microseisms associated with the Incidence of the, S. K. Banerji, 576
Southend-on-Sea Public Museum, gift to, by Major Weber, 133
Sovereignty, Prof. A. D. Lindsay, 108
"Space-time," Prof. Alexander's Notion of, J. A. Smith, 953; The Curvature of, Radial Velocities and, Dr. L. Silberstein, 347
Spain, Archæological Discoveries in, by Mrs. Wishaw, 364
Spathidium spathula without Endomixis or Conjugation, The Longevity of, L. L. Woodruff and E. L. Moore, 112
Special Libraries and Information Bureaux, Conference of, 389
Species and Chromosomes, Prof. R. R. Gates, 353
Spectra: of various Hæmoglobins and their Relative Affinities for Oxygen and Carbon Monoxide, The Correlation between the, Prof. J. Barcroft, M. L. Anson, A. E. Mirsky, and S. Oinuma, 809; Intra-atomic Fields in, Evidence of, Hansen, Takamine, and Werner, 447; Isotopes and, Nagaoka, Sugiura, and Mishima, 699
Spectrohelioscope, The: F. Stanley, 683; Prof. G. E. Hale, 628
Spectrometer, A New, Bellingham and Stanley, Ltd., 839
Spectroscopy and Atomic Structure, Dr. P. D. Foote, 731
Spheroidal Wave Functions, Dr. J. W. Nicholson, 881
Spiders of the Madeira Islands, The, Prof. T. D. A. Cockerell, 11
Spinning Projectiles, The Drift of, J. W. Campbell, 31
Spinoza, Descartes and Maimonides, Dr. L. Roth, 785
Spiral and Structureless Nebulæ, Prof. C. D. Perrine, 170
Spiritualism, Experiences in, with D. D. Home, the Earl of Dunraven, 638
Spitsbergen, Surveys in, R. A. Frazer, 483
Spray Liquids, Surface Tension of, Woodman, 587
Stanford University, Cal., Prof. A. Findlay to visit, 486
Star: A New Variable, with a Period probably very Short, A. Brun, 810; Clusters, Spiral Structure in, Dr. P. ten Bruggencate, 100
Stark Effect: The, on Fundamental (Bergman) Series, Dr. T. Takamine, 433; The Inverse, Dr. R. Ladenburg, 731
Stars: Absolutely Bright and Faint, The Difference of Velocity between, J. H. Oort, 264; Giant, A Possible Explanation of the Behaviour of the Hydrogen Lines in, Profs. K. T. Compton and H. N. Russell, 86; Masses of the, E. B. Wilson and W. J. Luyten, 847; Masses of, Radiation and, Prof. H. Vogt, 480; of Different Spectral Types, Relative Numbers of, K. G. Malmquist, 514; of Type O, The, Dr. J. S. Plaskett, 622; The Ages and Masses of the, Dr. J. H. Jeans, 828; The Luminosities of the, Dr. J. K. E. Halm, 802; The Pressure in the Reversing Layer of, and Origin of Continuous Radiation from the Sun, Prof. Megh Nad Saha, 155; Variable, S. Shinjo and T. Araki, 871
State, The, and Productive Research, J. W. Williamson, 705
Statics, Graphic, Elements of, Prof. C. W. Hudson and Prof. E. J. Squire, 674
Statique et résistance des matériaux, Prof. P. Montel, 120
Steam: Engines, The Thermal Efficiency of, Capt. H. Riall Sankey, 913; -nozzles, Third Report of the Research Committee, 24
Steel: Electric, The Manufacture of, F. T. Sisco, 150; High-speed Tool, M. A. Grossmann and E. C. Bain, 699; Manufacture, Electrothermic Processes of, 150; Stainless, J. G. Hopcraft, 801; The Metallurgy of, F. W. Harbord and J. W. Hall. Seventh edition. Vol. I.: Metallurgy, F. W. Harbord; Vol. II.: Mechanical Treatment, J. W. Hall, 235
Steels, Manganese, J. A. Jones, 517
Stellar: Atmospheres, Convection Currents in, C. E. St. John and W. S. Adams, 847; Distribution, Prof. H. Shapley, 622; Motions, A Study of, Dr. G. Strömberg, 798; Spectra: Distribution of Energy in, J. Baillaud, 100; The Distribution of, Dr. C. G. Abbot, 945; Variability, Prof. La Rosa's Theory of the Cause of, Prof. La Rosa, 550; Velocities, Statistics of, Prof. F. H. Seares, 390
Steric Hindrance and Complex Ring Compounds, K. von Auwers, 874
Sterioisomerism, Jubilee of the Modern Doctrine of, 652
Stimuli in Plants, Transmission of, Prof. H. H. Dixon, 626
Stokes-Einstein Law for Diffusion in Solution, The, Christina C. Miller, 773
Stone Implements from Texas, Dr. C. Peabody, 946
Stonehenge: Archæology of, 634; Proposed Burials at, 364; Prohibition of Burials at, 441; Recent Work at, Lt.-Col. W. Hawley, 438, 503; Prof. A. H. Sayce, 503; The Stones of, a Full Description of the Structure of its Outworks, E. H. Stone, 634

Stratified Finds on the North Kent Coast, J. P. T. Burchell, 878
Streatfeild Memorial Lecture, The, J. L. Baker, 735
Stresses in Framed Structures, 7
String Galvanometer, A New Form of, Prof. E. Wilson, 146
Structural Members and Connections, 7
Subject Index to Periodicals, The, 1917–1919. L: List of Periodicals Indexed and Author Index, 346, 402
Submarine Cable between New York and the Azores, Laying of a, 512
Substance and Function and Einstein's Theory of Relativity, Prof. E. Cassirer. Translated by Drs. W. C. and M. C. Swabey, 187
Subterranean Hydrology, F. Diénert, 211
Suez Canal, The Biology of the, Prof. J. Stanley Gardiner, 520, 866
Sulphur: Liquid, Some Electrical Properties of, D. H. Black, 76; New Pharmacological Observations with, L. Sabbatani, 559; Suspensions, The Colour of, Dr. E. T. Paris, 827; Vapour: Absorption Spectrum and Constitution of, Predissociation of Molecules, Prof. M. Henri and M. C. Teves, 894
Sulphuretted Hydrogen: Fermentation in the Black Sea, B. Issatchenko, 147; The Production of, by Fermentation in the Black Sea, B. Issatchenko, 205
Sulphuric Acid: Formation in Leaden Chambers, The Reversibility of the Reactions of, A. Graire, 396; The Concentration of, J. W. Parkes. ("The Manufacture of Acids and Alkalis," by G. Lunge. Completely revised and rewritten under the editorship of Dr. A. C. Cumming. Vol. 3), 818; The Manufacture of (Chamber-process), W. Wyld. ("The Manufacture of Acids and Alkalis," by G. Lunge. Completely revised and rewritten under the Editorship of Dr. A. C. Cumming. Vol. 2), 818
Sun: the Diameter of the, Observations on, G. Armellini, 148; Observations of the, made at the Lyons Observatory, J. Guillaume, 299
Sun's Atmosphere, The Pressure and Currents in the, C. E. St. John and H. D. Babcock, 847
Sunshine and the Dry Fly, J. W. Dunne, 531
Sun-spot Activity, 254
Sun-spots: and Australian Rainfall, E. T. Quayle, 523; Rainfall and, Lake Level in Relation to, Dr. F. Dixey, 659
Super-conductivity, A Theory of, E. Kretschmann, 292
Surface Tension and Fine Particles, Dr. E. F. Burton, 502
Surfaces portantes, Sur la théorie des, M. Roy, 566
Surveys from the Air: The Present Position, Sir C. F. Close, 195
Suspensions, The Stability of, I., W. O. Kermack and W. T. H. Williamson, 954
Sweden: Rainfall Map of, A. Wallen, 588; The Water-power of, S. Norlindh, 910
Sydney: The Technological Museum of 621; University: resignation of posts of warden and registrar by H. E. Barff, 71; forthcoming appointment of a chief executive officer, 629
Syndosmya alba and *Cardium fasciatum*, On Early Sexual Maturity in the Molluscs, Dr. J. H. Orton, 244

Tale of Two Cities, A, H. S. Pritchett, 795
Tannins, The Physiological Rôle of the, F. Picard, 739
Tantalum and Niobium, The Precipitation of, by Cupferron and their Separation from Iron, H. Pied, 811
Tartaric Acid: Hydrated Active, M. Amadori, 595; The Rotatory Dispersion of, W. T. Astbury, 122; Prof. T. M. Lowry and Dr. P. C. Austin 430
Tasmania, The Aborigines of, Sir T. W. Edgeworth David, 551
Technical: Colleges, Prospectuses of, 450; Writing, T. A. Richard. New edition, 640
Technically Trained Men, The Pay of, 477
Télégraphie sans fil, La: ses applications en temps de paix et pendant la guerre, J. Verdier, 241
Telegraphy of the Future, D. Murray, 943
Telepathy, Instances of, Mrs. H. Sidgwick, 906
Telephone: Circuit Diagrams: A Handbook of, with Explanations, J. M. Heath, 606; Systems, Automatic, W. Aitken. Vol. III., 533
Telephones, Automatic, F. A. Ellson, 428
Telescopes in the Southern Hemisphere, 655
Tellurium: The Suboxide of, A. Damiens, 774; The Vapour Pressure of, J. J. Doolan and Prof. J. R. Partington, 182
Temperature of the Air, The Maximum Recorded, and its Circumstances, Prof. T. Eredia; L. C. W. Bonacina, 294
Tensile: Strength, Temperature, and Cold Work in some Pure Metals and Single Solid Solutions, Relationship between, D. H. Ingall, 522; Testing, Recent Developments in, J. V. Howard and S. L. Smith, 881
Tensorrechnung, Einführung in die, Prof. H. Rothe, 565
Terephthal Green and Terephthal Brilliant Green from Cymene, The Synthesis of, M. T. Bogert and P. S. Nisson, 920
Termites and their Intestinal Protozoa, Symbiosis between, L. R. Cleveland, 22
"Terrella," The, 722
Terrestrial: Field at Val-Joyeux, near Paris, The Value and Variations of the, C. Mourain, E. Salles, and G. Gibault, 111; Magnetic Disturbance, The 27-day Period (Interval) in, Rev. A. L. Cortie, 31: Magnetism: in France, Dr. C. Chree, 951; The Evidence of, for the Existence of the Highly Ionised Regions in the Upper Atmosphere, Prof. S. Chapman, 918
Tertiary: Radiation produced by Impacts of Photo-electrons, The Theory of the, G. L. Clark and W. Duane, 112; X-rays, Absorption Measurements of certain Changes in the Average Wave-length of, S. K. Allison and W. Duane, 112
Testis and Ovary, Transplantations of, K. Sand, 623
Tetrachlorophthalic and Tetrabromophthalic Acids, The Action of, on Turpentines, A. Haller, 31
Textile Fibres: The, their Physical, Microscopical, and Chemical Properties, Dr. J. M. Matthews. New edition, 421; The Physical and Physico-chemical Problems relating to, Dr. A. E. Oxley; Dr. W. L. Balls and others, 27; The Study of, F. Summers, 421
Thallium Vapour, Absorption and Dispersion of, Prof. A. L. Narayan and D. Gunnaiya, 881
Thallous Thallic Halides, A. J. Berry, 731
Thermal: Activation by Collision, Hinshelwood and Hughes, 696; Dissociation of certain Carbonates, G. Mazzetti, 631; Fractionation of the Gaseous Products of the Pyrogenic Decomposition of some Definite Compounds, The, P. Lebeau, 210
Thermionic: Emission from Systems with Multiple Thresholds, Prof. O. W. Richardson, 145; Tubes in Radio-Telegraphy and Telephony, J. Scott-Taggart. New edition, 413; Valve, The, and its Development in Radio-Telegraphy and Telephony, Prof. J. A. Fleming. New edition, 413
Thermochimie, Prof. F. Bourion, 240
Thermodynamique: Énergétique: Théorie cinétique des gaz (Cours professé à la Sorbonne), Prof. A. Leduc, 344
Thermopile used for Measuring Star Magnitudes, The, J. Schilt, 390
Thiocyanates and Cyanates, K. C. and Mrs. D. F. H. Bailey, 146
Thorium: B+C, The β-ray Spectrum of, Dr. W. Pohlmeyer, 874; -X, The Quantitative Estimation of, F. Gazzoni, 845
Thread Blights, T. Petch, 729
Thunderstorm, The Electric Field of a, and some of its Effects, C. T. R. Wilson, 918
Thunderstorms, The Electricity of, Dr. G. C. Simpson, 890
Tidal: Constants, Harmonic, Perturbations of, Dr. A. T. Doodson, 738; Institute of the University of Liverpool, Report of the, 548; Power Generating Station at Aber Vrac'h, near Brest, The Construction of a, 512
Timber in the Sea, The Protection of, 744
Time: Measurement: an Introduction to Means and Ways of Reckoning Physical and Civil Time, L. Bolton, 531; The Determination of, and the Modified Use of the Method of Corresponding Heights, G. Bigourdan, 147
Tinstone, Origin of, C. Raeburn, 23
Tissue: Culture: Dr. A. Carrel and others, 178; in Relation to Growth and Differentiation, T. S. P. Strangeways, 856; "in Vitro," Technique of, T. S. P. Strangeways, 856; Growth, 709

Tissues, Living, The Preservation of, J. Amar, 299
Titanium, Ionised, Regularities in the Spectrum of, Nalini Kanta Sur, 611
Tittigarcta crinita, Dist., The Gippsland Hairy Cicada, H. Ashton, 212
Tobacco, The Genetics of, G. L. C. Howard and Kashi Ram, 588
Tokyo, The Scheme for Rebuilding, 725
Tornado, Destructive, in the U.S.A., 19
Town's Gas, Production of, by the Regenerative Gasification System, Dr. M. W. Travers and Clark, 65
Tradescantia fluminensis Vell., Leaf and Stem Anatomy of, Prof. J. H. Priestley and Miss Lorna I. Scott, 109
Trans-Canadian Excursion of the British Association and the International Mathematical Congress, 768
Triaminopropane, 1.2.3, Sir William J. Pope and F. G. Mann, 111
Trichlorophenylmethyliodosalicylic Acid, The Use of, as an Antiseptic, 200
Triton cristatus: Regeneration of the Whole from Half the Cut Surface of an Extremity in, etc., P. Weiss, 184; Utilisation of, for the Destruction of the Larvæ of Anopheles, L. Garofolini, 667
"Trivet, Right as a," Five- (and Six-) Point Support, Sir G. Greenhill, 463
Tropical: Colonisation and the Future of Australia, Prof. J. W. Gregory, 314; Medicine in the Southern United States, Dr. A. C. Castellani offered the University professorship and the directorship of the new school of, 806; Plantation Crops, Diseases of, Dr. Doidge and others, 208; Revolving Storms, The Origin of, Capt. D. Brunt, 389
Tsetse-fly Investigations in Nigeria, Drs. L. Lloyd, W. B. Johnston, W. A. Young, and H. Morrison, 694
Tubes filled with Air or other Gas at Low Pressure, Prof. Risler, 834
Tübingen University, Prof. Gerlach invited to the chair of physics in, 952
Tulum: An Archæological Study of the East Coast of Yucatan, Dr. S. K. Lothrop, 893
Turtle, Culture of an Endamœba from the, H. P. Barret and Nannie M. Smith, 172
Twentieth-century Universities of England, 921
Tycho Brahe's Observations, 151
Tychonis Brahe Dani opera omnia, Edidit I. L. E. Dreyer. Tomus X., 151

Ultraviolet: Spark Spectra of some of the Elements, The, R. J. Lang, 31; Spectro-photometry, Prof. T. R. Merton, 737
Underblown Pipes, D. Gunnaiya and G. Subrahmaniam, 773
Unemployment Insurance: Problems of, 700; The Limits of, Prof. J. R. Commons, 700
Union Observatory, Johannesburg, Yale Observatory to set up a 26-inch photographic telescope in the grounds of, 655
Universe, The Depths of the, Prof. G. E. Hale, 3
Universities: of Great Britain and Ireland, Annual Conference of the, Report of the, 71; Twentieth-century, of England, 921
University: *Bulletin*, The, 107; College: Cork, Dr. J. Reilly appointed professor of chemistry at, 952; London, Calendar for 1924–25, 736; of the South-west: Exeter, Prof. W. H. Moberly appointed principal of, 843; Reports for 1923–1924, 880; Finance, University Staffs and, 453; Students in Europe, Safeguarding the Health of, Jean Willems, 736
Upper: Air: Correlation between Pressure and Temperature in the, with a Suggested Explanation, W. H. Dines, 810; Observations, 910; Hunter River, The Physiography and Geology of the, W. R. Browne, 559; Permian Coleoptera and a New Order from the Belmont Beds, N.S.W., Dr. R. J. Tillyard, 919
Uranium: I and Uranium II, The Ranges of the α-Rays from, Dr. B. Gudden, 553; Nitrogen and, Dr. P. D. Foote, 789; Thorium, and Radium, Need for the Redetermination of the Atomic Weights of, Dr. A. S. Russell, 717
Uranus, The Planet, W. F. Denning, 170
Urea: from Carbon Dioxide, The Synthesis of, and Ammonia under Atmospheric Pressure, K. C. Bailey, 775; Influence of, used as Manure, on the Reaction of the Soil, C. Brioux, 811
Uric Acid: Action of Catalysts on the Oxidation of, Copper and Cuprous Urate, L. Piaux, 811; in the Pieridæ: a Quantitative Study, V. B. Wigglesworth, 809
U.S.A.: Acting-Secretary of Agriculture for the, Prof. C. F. Marvin appointed, 654; Educational Directory, 1924, 395; Education, etc., in the, gift for, J. B. Duke, 916; Educational Research in the, 107; gifts for Education in, G. Eastman, 880; Hourly Rainfall in, H. G. Carter, 552; S. D. Flora, 552; List of Source Books, 952; National Research Council: Activities of the, 133; foundations of fellowships and scholarships, 370; Orchard Heating in the, 370; Recent Developments in Non-ferrous Metallurgy in the, with special reference to Nickel and Aluminium-bronze, W. M. Course, 452; Semi-rigid Airship Construction and Operation in the, 620
Ussoi Landslip of 1911, The, J. Préobrajensky, 873

Vacuum: Pump, A High, Dr. G. West, 446; Tube: Discharge, The, Sir J. J. Thomson, 102; Discharges, Oscillations in, Prof. R. Whiddington, 193
Vasectomy and Similar Operations, K. Sand, 623
Vectorial Dimensions, J. F. S. Ross, 773
Vegard's Theory of the Aurora, R. d'E. Atkinson, 881
Vegetable Proteins, Dr. T. B. Osborne, 822
Vegetative Propagation: in the Tropics, 556; of Plants, Edinburgh Conference of the, 179
Velella at Port Erin, Sir W. A. Herdman, 124
Verse: The Biology of, Prof. E. W. Scripture, 825; The Physical Nature of, Prof. E. W. Scripture, 534; Rev. E. W. Lummis, 682
Vertebrates, Land, The Origin of, Prof. E. S. Goodrich, 935
Vesuvius: Activity of, 1903–1921, 851; and of Solfataras, Eruptive Gases of, The Radioactivity of the, and their Influence on the Development of Bacteria and the Higher Plants, J. Stoklasa and J. Penkava, 774; Eruption of 1906, The: Study of a Volcanic Cycle, F. A. Perret, 851
Vibration in Engineering, J. Frith and F. Buckingham, 785
Victoria: and Albert Museum, E. R. D. Maclagan appointed director and secretary of the, 20; Lake, and the Flow of the Yala River, Dr. G. D. Hale Carpenter, 311
Vienna Academy of Sciences: Dr. E. S. Dana elected a corresponding member of the, 443; Prof. R. Zsigmondy elected a corresponding member of the; receipt by the, of papers as proof of priority, 253
Vine Phylloxera, Existence of various Species of, and the Susceptibility of American Vines to Phylloxera, M. Topi, 595
Visibility Function, The Relative, K. S. Gibson, 329
Vivarium and Aquarium Keeping for Amateurs: Practical Guide to the Hobby, A. E. Hodge, 412
Volcanic: Gases, Emission of, Lord Rayleigh; Dr. A. A. Robb; Dr. G. P. Bidder; J. Place, 50; Islands in the China Sea, 391

Wales, National Museum of, Dr. R. E. M. Wheeler appointed director of the, 169
Waller Memorial, The proposed, 944
Wandle, The Book of the: the Story of a Surrey River, Dr. J. M. Hobson, 532
War: the Great, History of, based on Official Documents. Medical Services, General History. Vol. 4: Medical Services during the Operations on the Gallipoli Peninsula, etc., Maj-Gen. Sir W. G. Macpherson and Maj. T. J. Mitchell, 678; Vol. 3: Medical Services during the Operations on the Western Front in 1916, 1917, and 1918; in Italy; and in Egypt and Palestine, Maj.-Gen. Sir W. G. Macpherson, 154
Warmth-loving Plants in the Mur District, The Dispersal of, L. Lämmermayr, 300

Waste : Heat Boilers and Vertical Retort Gas Installations, 65 ; Materials : Uses of, the Collection of Waste Materials and their Uses for Human and Animal Food, in Fertilisers and in certain Industries, 1914–1922, Prof. A. Bruttini, 460
Water : is separated from Silicates, Determination of Temperatures at which, J. Orcel, 955 ; -power Installations, Determination of the most Economic Size of Pipe Line for, H. H. Jeffcott, 775 ; Supplies, Emergency, for Military, Agricultural, and Colonial Purposes, A. Beeby Thompson, 378 ; The Expansion of, while Freezing, Prof. A. P. Laurie, 882 ; -vapour, The Viscous Properties of, C. J. Smith, 74 ; Waves, The Formation of, by Wind, Dr. H. Jeffreys, 881
Watt, James, Presentation of the contents of the attic workshop of, to the Science Museum, South Kensington, 834
Wave : -lengths, Comparison of, with a Fabry and Perot Étalon, H. D. Babcock, 276 ; -meter, A Self-contained Standard Harmonic, D. W. Dye, 73 ; -power Transmission, Lieut. E. A. Barclay-Smith, 392
Waves, Wind and, A. Mallock, 679
Weather : Abnormal, or Abnormal Wind Circulation, Plea for the Central Publication of Reports of, S. Ferraz, 288 ; Forecasting, Barogram Analysis in, F. Vercelli ; L. C. W. Bonacina, 393 ; in West Indies, O. L. Fassig, 446 ; *Map* of the Meteorological Service of the Dominion of Canada, July, 442 ; The, in July, 98 ; January to June, 59
Weber-Parkes prize and medal, the, presented to Prof. A. Calmette, 654
Welsh National School of Medicine, Dr. E. H. Kettle appointed professor of pathology and bacteriology, 180
West Indies, Weather in, O. L. Fassig, 446
Western : Australia, Stratigraphy of, E. de C. Clarke, 873 ; Highlands ; The Peaks, Lochs, and Coasts of the, Penned and Pictured with One Hundred Photographs, A. Gardner, 154
Whales of the Genus Balænoptera, Cestodes from, H. A. Baylis, 917
Wheat, Yeoman II., to be placed upon the market, 252
White : Gilbert, Fellowship, gift to the, by the Earl of Dartmouth, 693 ; "Indians" : of Panama, The Reputed, 870 ; on the Chucunaque River, Report on the, 761
Wild : Animals in Captivity, Diseases of, 343 ; Mammals and Birds : Disease in Captive, Incidence, Description, Comparison, Dr. H. Fox, 343
Willow-grouse in Norway, The Food of the, Dr. J. Holmboe, 656
Wind : above Fog, Estimation of, L. F. Richardson, 204 ; and Waves, A. Mallock, 679 ; Wave, and Swell in the North Atlantic Ocean, Dr. Vaughan Cornish, 394
Winds : and Temperature in a Dry Atmosphere, Sir Napier Shaw, 954 ; of Central Europe, Dr. A. Defant, 552
Winters, Cold, in South-Central Europe, J. Maurer, 516
Wireless : Detectors with Solid Contact, The Influence of the Pressure on the Working of, J. Cayrel, 335 ; Electric Rays, Why, can bend round the Earth ? Sir Joseph Larmor, 650, 947 ; Possibilities, Prof. A. M. Low, 413 ; Reception and Transmission to and from a Moving Train, 133 ; Telegraphy : in Relation to Atmospherics, A Brief History of, Prof. W. H. Eccles, 917 ; Receiving Apparatus of, Meteorological Conditions and the Appearance of certain Atmospheric Disturbances in, R. Bureau and A. Viant, 396 ; Transmissions Abroad, The Radio Society and, 134 ; Transmission of, Geophysical Influences on the, Prof. E. V. Appleton, 918
Wisconsin, North Central, Soil Survey of the South Part of, 202
Witchcraft in Medieval India, W. Ivanow, 171
Witwatersrand, University of the, Calendar of the, 370
Wood : -fibres of some Australian Timbers : Investigated in Reference to their Prospective Value for Paper-pulp Production, R. T. Baker and H. G. Smith, 190 ; Products, T. W. Jones, 491 ; Protecting, against Termites, T. E. Snyder, 551
Wood's Hole, Mass., Marine Biological Laboratory at, to be developed, 169
Woollen and Worsted Industries, British Research Association of the, Awards of the, 443
World : Aeroplane Flight, Completion of the, 513 ; Power Conference, The, H. Hirst, 59

Xerophytic Plants, Transpiration of, H. W. Wilson, 837

The Imperial Institute Bill.

A GOVERNMENT Bill to effect the reorganisation of the Imperial Institute has been introduced into the House of Lords by Lord Arnold and there passed its second reading. This Bill will be welcomed, as it should help the development of that Institute to a position worthy of the group of museums and scientific institutions at South Kensington. The Colonial Office Committee of Enquiry into the Imperial Institute in 1923 recommended the abolition of its galleries, the limitation of the work of its laboratories to preliminary investigations of raw materials, and the reduction of the Institute to a clerical bureau. This scheme was approved by the Imperial Economic Conference, some members of which were unacquainted with the facts, as one of them has since stated. If the majority report of the Colonial Office Committee had been promptly carried into effect, the Imperial Institute collections would have been scattered and the galleries occupied by a War Museum, which, however desirable, would have been out of place in South Kensington on a site allotted to the development of the industrial arts and science by the Commissioners for the Exhibition of 1851. The majority report of the Committee was opposed by a strong minority, and has since been widely condemned.

The Bill, in agreement with the minority report, is based on the retention of the Imperial Institute galleries and the amalgamation of the Mineral Resources Bureau with the Mineral Department of the Institute. The Bill proposes the transfer of the management of the Institute from the Colonial Office to the Department of Overseas Trade, which is a branch of the Board of Trade, and the establishment of a new Board of Governors consisting of representatives of the Dominion of Canada, Australia, New Zealand, South Africa, the Irish Free State, Newfoundland, and India,

and representatives of the Treasury, the Board of Trade, the Colonial Office, the Ministry of Agriculture and Fisheries, the Department of Overseas Trade, and the Department of Scientific and Industrial Research, and not more than ten scientific and commercial representatives, including one from the Royal Society and not less than three Governors of the Mineral Resources Bureau.

The property would be vested in six Trustees, all of whom would be members of the Government. As the Imperial Institute was erected and endowed largely by public subscription and its main service would be to the smaller colonies, it is desirable that some of the Trustees should be unofficial, and one of them should represent directly the Empire overseas. More confidence in this Board of Trustees would be felt if only three of them were members of the Government, and the other three included a representative of the Dominions, the president of the Association of the British Chambers of Commerce, and some such authority as the Governor of the Bank of England or the president of the Institution of Mining and Metallurgy.

The Board of Governors would act through a Managing Committee which would be aided by various advisory councils or committees, including one on minerals, and would be associated with a Laboratory Committee, including representatives of the Department of Scientific and Industrial Research and of the Royal Society.

This Bill renders possible the development of the Imperial Institute as a great museum and research institution for the investigation of the natural resources of the British Empire overseas. The reconstituted Institute might develop into an organisation capable of giving important help in the investigation of the economic geology and mineral resources of the Empire outside Great Britain. The Bill is, however, unsatisfactory in two respects in which the terminology of the abandoned majority report has passed into the Act. That report recommended the appointment of a Laboratory Committee, the functions of which would render the Institute laboratories futile. The Laboratory Committee, according to the resolution of the Imperial Economic Conference, was proposed "to ensure that the reconstituted Imperial Institute may in future undertake in its laboratories only preliminary investigations of raw materials for the purpose of ascertaining their possible commercial value. . . ." If any more extensive research or investigation be required, it would be the duty of the Laboratory Committee to see that the material were sent to some other authority in Great Britain or "elsewhere within the Empire."

This proposal would, if carried into effect, seriously lessen the usefulness of the Institute. Many of the most interesting materials it might expect to receive would be submitted in confidence, which would not be felt if the material were to be distributed to University or public laboratories for investigation. The various Departments of the Institute would doubtless include experts in some branches of its work, and they would sometimes have to send on material for investigation to people less competent to deal with it than themselves.

The scheme would probably also involve risk of trouble between the several committees of the Institute. The Managing Committee and the Mineral Committee would naturally desire to escape from the restriction to preliminary work, though ready to seek the co-operation of authorities who might be specially competent to deal with special materials or problems. The Managing and the Mineral Committees might therefore be in frequent friction with the Laboratory Committee, the duty of which would be to see that the other committees and the Institute staff committed nothing beyond an elementary commercial examination. The clause in the schedule enumerating the purposes of the Institute "To conduct preliminary investigations of raw materials and, when it may be deemed advisable, to arrange for more detailed investigation by appropriate scientific or technical institutions," therefore, might well be amended by omission of the word "preliminary" and the alteration of "more detailed" into "further" investigation.

The main discussion hitherto has been over the galleries, the great educational value of which has been frequently pointed out in NATURE. The new Bill empowers the governing body to maintain galleries for the exhibition of Empire products. If the Bill be passed as now worded, some future official might maintain that collections of commercial samples in the Dominion offices in different parts of London would satisfy this clause, and this Bill might be used to give effect to the very policy which it is understood that the Government at present in office has abandoned.

The schedule stating the purposes of the Imperial Institute does not even refer to the Institute galleries. The only clause dealing with collections states that the Institute is "to organise, so far as practicable, exhibitions of Empire products." This clause is quite inadequate as a statement of the duties of the Institute in connexion with its public exhibition galleries. It implies that all the Institute should arrange is exhibitions of commercial samples, which, as the Colonial Office Committee recommended, might be peripatetic.

The clause should be amended to state definitely that the Institute should retain its galleries at South Kensington and maintain in them exhibitions of the products of the Empire, so displayed as to demonstrate their nature and uses, and to illustrate adequately the geographical conditions and material resources of the British Empire.

A few amendments are therefore desirable to prevent ambiguity. Without these changes, there is the risk that the Act will, in effect, be used to return to the recommendations of the majority report of the Colonial Office Committee of Enquiry, and thus to prevent the Imperial Institute from fulfilling the important functions proposed for it by its far-seeing and generous founders.

The New Astronomy.

The Depths of the Universe. By George Ellery Hale. Pp. xv+98. (New York and London: Charles Scribner's Sons, 1924.) 7*s.* 6*d.* net.

ASTRONOMY is a subject which, in spite of the delicate refinement of its observations and the severe technicality of its mathematical processes, yields results which can be fairly apprehended by the general educated public,—results moreover which, though apparently far removed from humanity, yet invariably arouse a human interest. There was a time when it appeared to be a completed, so to speak, perfected science, in which little of a revolutionary character was to be expected. But modern discoveries in physics have changed all that; and discoveries are yearly being made which are likely to enlarge our ideas about the constitution of the heavens in a striking and revolutionary manner.

Part of this progress is due to the enthusiastic workers, and the great resources provided for them, on the other side of the Atlantic; where lavish provision has been made for experimental resources, where sufficient mathematical skill is available for devising methods and interpreting results, and where the clearness of the air on mountain-tops has been utilised after the enterprising manner characteristic of the American nation.

Among the workers in novel directions the name of George Ellery Hale is held in honour throughout the civilised world; and the whole world hopes for his restoration to health, so that he may continue to infect his co-workers with enthusiasm, and that he may have the joy of continuing the utilisation of the magnificent Observatory and laboratories on the top of Mount Wilson in California. Meanwhile he has been giving us the benefit of his powers of exposition in articles and discourses, some of which are being collected in small and illustrated books, one called "The New Heavens," and another, which has just been published, entitled "The Depths of the Universe." The main branches of the subject dealt with in this little volume are three in number. The first relates to the stars and star clusters, with some account of the remarkable and novel principles by which spectroscopic determination of excessive and otherwise hopelessly immeasurable distances can be made. The second relates to the nebulæ, and especially to the dark nebulæ discovered by the late Edward Emerson Barnard, of the Yerkes Observatory, whose lamented death has so recently occurred, and to whom the author pays an affectionate and admiring tribute. While the third chapter in the book gives further details about the author's own great discovery about the magnetic condition of the sun and its spots, a subject begun to be expounded in one of the chapters of "The New Heavens," and now carried to a further stage.

The treatment throughout is of a popular character, and all recent advances are linked on to the history of the past. Thus in the first chapter, which is specially on "The Depths of the Universe," Prof. Hale begins with Galileo and the first telescope, and carries the history rapidly forward, through Herschel, to the determination of stellar and globular-cluster distances by Dr. Harlow Shapley, of Harvard.

The main theme of the first chapter is the size and shape of our stellar cosmos, familiar to all as "the Milky Way," which must be of unexpectedly vast extent if the immensely distant globular clusters form any part of it. Outstanding questions about the spiral nebulæ are not dealt with; but many details are given about other objects, and especially the dark nebulæ emphasised by Barnard. Some of them are regarded as immense clouds of dust driven away by the pressure of light, but held together, even in diffuse form, by their own gravitation. It is suggested that many of the nebulæ are only luminous because they reflect, or fluoresce in, the light of luminous stars in their neighbourhood. This seems specially to apply to the great nebula in Orion. But the globular star clusters are of a different order, perhaps more analogous to the constellation of Orion itself, the great cluster or crowded and enormous constellation in Hercules being apparently at a distance of 36,000 light-years.

Incidentally I would here express a hope that the light-year, as a unit of stellar distance, may be generally employed instead of the less satisfactory parsec, as a cosmic measure. Distances can very properly be expressed in terms of speed and time: that is indeed the fundamental way of measuring them, and far superior to anything dependent on the copying of an arbitrary unit such as a yard or a metre. Parallax,

dependent on the length between earth and sun, is absurdly incompetent to express enormous distances: the period of earth's revolution combined with the speed of light is better. It seems impracticable to get away altogether from the earth, in devising a cosmic unit, but the periods of the earth's rotation and revolution are universal terrestrial units of time; while as to the velocity of light, it appears to be about the only absolute thing we know.

To return from this brief digression. In order to emphasise the enormous number of stars now accessible to photography, Prof. Hale gives an interesting series of photographs, with different exposures, of a small region in Auriga near a third magnitude star. The first exposure is long enough to show stars down to the ninth magnitude, but none are visible, only the big one. The second exposure would show twelfth magnitude stars, and there are now five or six on the plate. A further exposure, long enough to bring out those of the fifteenth magnitude, shows something like fifty in all. Exposing long enough for seventeenth magnitude stars, more than two hundred appear; and when stars of the eighteenth magnitude are allowed time enough to impress the plate, the field is crowded with a number like four hundred.

The chapter on sun-spots begins with ancient observations, and continues, through the discovery of Faraday of the rotatory effect of magnetism on light, to the supplementary great discovery of Zeeman; and so on to its quite recent application by Prof. Hale to ascertain the nature of the hydrogen vortices in the upper layers of the sun, which appear to be more or less closely associated with the deeper-seated sun-spots below. Every one now knows that the lower regions of a sun-spot were proved to be powerfully magnetised by Hale's discovery of the Zeeman effect in the light emitted by them. This discovery has now been extended into most interesting detail, by the splendid power of the 150-ft. tower telescope erected on the top of Mount Wilson, with a spectroscope 75 ft. long sunk in a well below it. This telescope forms an image of the sun 16½ in. in diameter. A small sun-spot can be focussed on the slit of the 75-ft. spectroscope, so as to fall on a Rowland grating at the bottom of the well; and, though the slit is only three thousandths of an inch wide, the light passing through it is returned as a long spectrum extending 40 ft. from red to violet—a spectrum of the second order, on photographs of which observations can be made, with complete polarimetric proof that the interior of a spot produces precisely similar effects to those of an ordinary powerful longitudinal magnetic field.

The result has been to confirm the importance of the eleven-year solar period, and to show that it is only half the real period, when not merely the appearance of spots but their magnetisation is taken into account. Sun-spots are known to begin far from the solar equator during a minimum, and gradually to form nearer the equator. It would be simple if we could say that all those in the northern hemisphere of the sun are magnetised one way, and all those in the southern hemisphere magnetised the other way, and that then in the next sun-spot period these directions were reversed. That is not true, though something like it is true. It is not true because sun-spots do not occur singly. They occur for the most part in pairs, the two components of each pair not being necessarily equally well marked. They might be likened provisionally to the two opposite whirls we see when a teaspoon is drawn across a cup of tea; those two whirls are united by a semicircular vortex below. It may be so in the sun, though that is not yet clear. Allowing the analogy, however, the teaspoon must be drawn one way in the northern hemisphere and the opposite way in the southern during one eleven-year period; but in the next eleven-year period these directions must be reversed, giving twenty-two years for the time of the whole cycle of changes.

Moreover, by their magnetic properties, Hale found it possible to discover invisible or submerged sun-spots. They are all deep-seated disturbances, far below the photosphere; and it is only when a hydrogen whirl in the upper regions coincides with the electronic whirl below, that they burst out as it were and become visible. A great slowly alternating magnetic disturbance is going on in the body of the sun, of a quite unknown character, and with a twenty-two year period. These great electrical whirls must have a profound meaning, not yet dissected out. We are so dependent on the sun for everything, that they may have an unexpected influence on terrestrial phenomena and earth life. Meanwhile, we only know of them—at least until quite recently—by the manifestation we call sun-spots, when whirls happen to extend into the upper regions of the solar atmosphere and so break through.

Discovery is still going on; and it is to be hoped that Prof. Hale and his co-workers may long continue to elucidate this portentous phenomenon, which has proved itself so much more law-abiding than anything in our terrestrial weather and storms appear to be. There are some analogies: there may even be some connexion, but at present we can only say that whatever may be the truth about cyclones in the earth's atmosphere, they certainly exist on a huge scale in the solar atmosphere, or solar substance—for the whole sun may be obedient to the laws of gases at that high temperature—and that probably much more remains to be discovered about both.

OLIVER LODGE.

Modern Chemistry.

Chemistry in the Twentieth Century: an Account of the Achievement and the Present State of Knowledge in Chemical Science. Prepared under the guidance of a Committee representing the Scientific Societies, with Dr. E. F. Armstrong as Chairman and Editor. Pp. 281. (London: Ernest Benn, Ltd., 1924.) 15*s.* net.

IT was a very happy thought which prompted the preparation of this impressive work under the guidance of a committee representing the scientific societies, with Dr. E. F. Armstrong as chairman and editor. No one even remotely interested in the achievements of chemical science who visits the Chemical Hall at the British Empire Exhibition can fail to be profoundly impressed by the display of chemical products which he sees there, but he will not perhaps so easily realise the important part which British scientific workers have played in building up the knowledge which rendered that display possible. To make the achievements of British chemists clear to all the world is the purpose of the book under review; and the purpose is realised most excellently in this series of monographs written by distinguished men of science and preceded by an introduction from the pen of the editor. After reading through the 280 pages or so of which the volume consists, one has a feeling of pride in the work which British chemists and men of science have accomplished.

In a series of two dozen articles there is told, in a language which all who have a moderate acquaintance with chemistry can understand, the story of the growth of chemical science during the past quarter of a century, as promoted more especially by the labours of British chemists. In his general introduction, Dr. E. F. Armstrong gives an excellently composed survey of the domain as a whole, and we get here the kernel of the succeeding specialised articles. The opening sections of the work deal with the physical basis of matter: the atom, the molecule, the ion (by Prof. I. Masson); the structure of the atom (Dr. E. N. da C. Andrade); crystallography (Mr. T. V. Barker and Sir Henry Miers); and X-ray analysis of crystals (Sir William Bragg). These articles give a very complete survey of the whole domain of atomics, sub-atomics, and atomic arrangement in crystals, and will convey an adequate knowledge of these subjects to those whose main interests lie in other directions.

The story of the rare gases of the atmosphere is told delightfully by Dr. Travers, who does not fail to point out the practical applications of argon and helium and neon, a matter in which the layman is always specially interested.

The almost autobiographical sketch, "Milestones in Organic Chemistry," by Prof. H. E. Armstrong, one would gladly have seen expanded to greater length. It is a piece of history which all younger students of chemistry should read and ponder. The reviewer feels that it should have been placed before, not after, the article on the chemistry of the carbon compounds by Prof. J. F. Thorpe, in which the author discusses with amazing skill almost the whole realm of organic chemistry. Stereochemistry might perhaps have received rather more space.

The "Chemistry of Colloids" (Dr. W. Clayton), "Catalysis" (Dr. T. P. Hilditch), and "Fats and Oils" (Mr. J. Allan), are brief but clearly written, and will be read with pleasure. The story of one of the most notable British contributions to organic chemistry, the work of the St. Andrews school on carbohydrates, is told, as one would wish it told, by the director of the investigations, Principal Irvine. The work of Scottish chemists also finds a prominent place in the "syntheses in the terpene series," and one regrets that no room was found for an article on stereochemistry, to the development of which past and present workers in University College, Dundee, have very largely contributed.

"Cellulose" (Mr. C. F. Cross), "Colour in Nature" (Mr. R. Furness), "Coal-tar Colours" (Mr. E. A. Bearder), all deal with sections of chemistry which have been largely developed by British chemists, and the enormous growth of the cellulose industries, production of viscose silk, etc., is one of the achievements of applied chemistry of which British chemists may be proud.

How great has been the progress in biochemistry and in branches related thereto, is well seen from the interesting series of articles by Drs. F. L. Pyman and T. A. Henry ("The Alkaloids"), by Dr. R. H. A. Plimmer ("The Nitrogenous Constituents of the Living Cell"), by Dr. A. Harden ("Biochemistry and Fermentation"), and by Sir John Russell and Mr. H. J. Page ("The Chemistry of the Soil and of Crop Production").

The development of the production and utilisation of alloys and of pottery and refractories is described by Prof. C. H. Desch and by Mr. Joseph Burton. Dr. H. F. Coward contributes an interesting article on "Flame, Fuel, and Explosion," in the study of which Great Britain holds a foremost place; and Sir Robert Robertson writes, as few others could write, on "Explosives." The achievements of British chemists since 1914 in this important section of chemistry are perhaps insufficiently known and insufficiently appreciated. "The Chemistry of Photography," by Sir William Pope and Mr. W. Clark, fittingly concludes the volume. The production of plates sensitive to light of all colours and capable of giving a correct

rendering of different colour tones is a great advance due to chemists, and in the production of the necessary dyes the Cambridge chemistry school occupies a prominent position.

For this great record of achievement all British chemists, at least, will be very grateful. For some reasons, perhaps, one might have preferred a more homogeneous composition from a single pen; but in the time available such a production would have been impossible. On the other hand, compensation is found in the fact that impressiveness is added to the tale, and a sense of the magnitude of the contribution of British workers to chemical science is given by the rapid change of subject and of literary style. This book should itself occupy a prominent position in the Chemical Hall at Wembley. ALEX. FINDLAY.

The Unity of Life.

Life: a Book for Elementary Students. By Sir Arthur E. Shipley. Pp. xvi+204. (Cambridge: At the University Press, 1923.) 6*s.* net.

SIR ARTHUR SHIPLEY'S little book is of an unusual type. "A year ago," he says in his preface, "the University Press asked me to write a book that would make students of elementary Biology think." Perhaps this is putting the matter a little strongly: it is scarcely just to suggest that students of elementary biology have not previously used their brains.

In his book Sir Arthur has tried to get away from the type system, and "to emphasise the unity of Life and the interrelation of living organisms." But he has still another purpose. "Finally, I venture to hope that this book will be not without interest to the public that is not preparing for examinations, and thank heaven that public is still in the great majority!"

What we lack in Great Britain is not school text-books of biology. On the contrary, there are too many, and they are usually too large, too well-organised and too informative. The great desideratum is a school *reader*—a book that might really interest a reasonable proportion of boys. "Life," if not the ideal book for the purpose, is at least of the desired type.

As the author's friends would expect, it is not only lucidly but engagingly written. You may tell a schoolboy a dozen times the percentage of water in the human body, and ten to one he will forget it. But when he reads "Even the Archbishop of Canterbury comprises 59 per cent. of water," he may remember. Or again, we are all taught that plants differ from animals in obtaining their nutriment from inorganic compounds. But the fact becomes vivid and fraught with consequences when we find it put as Sir Arthur puts it: "Their food comes to them as the roast geese in Heine's description of Heaven perpetually flew up to the angels offering them tureens of delicious soup;" but "the pleasure of the chase is denied them. Their food must be intolerably monotonous and extremely insipid. . . . Yet one hears no complaint."

The description of what a patch of grouse-moor would look like if magnified a hundred times is alone almost worth the price of the book. Admirable too is the dictum, "Fleas do not jump anything like the height or length that you think they do when you are trying to catch them." As a finale, we cannot refrain from quoting from the characteristic section on appetite. "Hunger undoubtedly induces people to eat food which a well satisfied man would not care to tackle. On the other hand, elaborate sauces and good cooking will often tempt a jaded appetite to put forth new efforts." Then we are told of the gastronomic preferences of Sydney Smith, Disraeli, Charles Lamb, and Dr. Johnson, and are hoping for more, when our author's conscience pricks him and he ends, "But I must stop dealing with these literary appetites, and get on with the next chapter." But meanwhile in another chapter he has made an important pronouncement on the same subject: "Man is the only animal that cooks its food, but the distance between the rough cookery of the Australian native or an Abyssinian and that of a French chef is almost immeasurable. The higher branches of cookery are one of the chief arts in which men invariably rise superior to women. . . ."

The book is not, however, without its faults. There is too much illustrative detail; the beginner will often find it difficult to see the wood for the trees. Especially in the more recent fields of research, the author has not always shown himself very critical. There are various errors and omissions which should be rectified. *E.g.*, on p. 71, the only positive statement made about the economic status of wild birds is that "they do a great amount of destruction in our gardens and orchards, and our cornfields." This may be so, but if there is one established fact in economic ornithology it is that the net benefit due to birds is enormous. The statement (p. 5) that the ductless glands are "the cause of many obscure diseases" is surely a lapse of our author's usually lucid pen. Many free-living protozoa (including the familiar Paramecium) are easily visible to the naked eye, in spite of Sir Arthur's statement to the contrary (p. 18). If he had wished to be very up-to-date he might have put in a word of warning against overdoing the fat-soluble vitamin in adult life.

However, Sir Arthur's book deserves a place in the library of every school department of biology; the professional biologist will read it with pleasure, and the layman with both pleasure and profit. But the author might make the second edition even better than the first.

Our Bookshelf.

The Principles of Insect Control. By R. A. Wardle and P. Buckle. (Publications of the University of Manchester: Biological Series, No. 3.) Pp. xvi+295. (Manchester: University Press; London: Longmans, Green and Co., 1923.) 20*s.* net.

THE literature dealing with the various methods of controlling injurious insects has now assumed such vast proportions that it is almost beyond the capacity of the economic entomologist to keep abreast of it. The necessity has arisen for periodic stocktaking of this accumulated information in order that the situation may be reviewed as a whole. Messrs. Wardle and Buckle have rendered a very distinct service in providing an excellent résumé of the present-day position with regard to insect control. In undertaking this task they have had the difficulty of sifting a literature often contained in unfamiliar languages, and scattered through a heterogeneous series of scientific, technical, and practical publications—many of which are relatively inaccessible. The collation and arrangement of the extracted information also presents certain difficulties, particularly on account of the wide and disjointed range of subjects dealt with.

These troubles have been surmounted by the authors very successfully, and they have managed to produce a very readable and coherent book. Their method has been to divide the volume into four parts, comprising altogether sixteen chapters. Part I. is devoted to biological means of control, including host-resistance, effects of climatic factors, disease, predaceous and parasitic insects, and insectivorous birds. All these different subjects are, for the most part, adequately treated. Part II. is concerned with insecticides, and is the longest and best section of the book. Part III. deals with mechanical control, including cultural methods, restriction of spread, storage of crops, and baits and traps. The section devoted to cultural methods might perhaps have been longer in view of their importance, and more examples of such methods enumerated. Part IV. is devoted to a short discussion of legislative control, and the book concludes with an appendix on various types of insecticide machinery, together with a very good classified bibliography. In a few words, it may be said that the volume should appeal to economic entomologists, since it covers the whole field of a subject which has not been previously surveyed in so comprehensive a manner.

(1) *Foundations, Abutments, and Footings.* Pp. xiv+414. 20*s.* (2) *Structural Members and Connections.* Pp. xviii+611. 30*s.* (3) *Stresses in Framed Structures.* Pp. xiv+620. 25*s.* Compiled by a Staff of Specialists. Editors-in-chief, Prof. George A. Hool and Prof. W. S. Kinne. (Structural Engineers' Handbook Library.) (London: McGraw-Hill Publishing Co., Ltd., 1923.)

THE three volumes before us belong to a series of six, which is intended to provide a complete work of reference covering the design and construction of modern civil engineering structures. A large number of prominent American engineers have co-operated in the production, and the commendable plan has been followed of making each volume, so far as possible, complete in itself. (1) The volume on foundations is copiously illustrated with examples taken from practice, and deals with all the matters which require consideration, from the preliminary investigation of the soil to the completed foundation, and includes such special points as underpinning, waterproofing, etc. Practically all types of engineering foundations are included. (2) The volume on structural members and connexions opens with brief statements of the general theory, occupying the first 171 pages; the remainder of the volume is taken up with the design of steel, cast-iron, wooden, and reinforced concrete members. The student who has mastered the elementary work on materials will find much of interest in the earlier part of this volume. The part dealing with design is exceptionally good, and contains much matter which is usually either omitted or receives scant treatment in British text-books. (3) The volume on framed structures also opens with a section on the general theory, occupying 158 pages. This part is by no means copied from the second volume, and includes methods of treating moving loads. The remainder of the volume deals with roof and bridge trusses, portal bracing, deflexion, secondary stresses, statically indeterminate frames, high buildings, towers, etc. The slope-deflexion method is generally employed for the solution of statically indeterminate frames in this treatise. Taking all three volumes, the authors have succeeded in producing an extremely valuable work of reference which cannot fail to be of service to civil engineers.

Theory and Practice of Mine Ventilation: a Text-book for Students and a Book of Reference for Managers and Under-managers. By Thomas Bryson. Pp. viii+255. (London: E. Arnold and Co., 1924.) 8*s.* 6*d.* net.

MR. BRYSON is an experienced teacher of mining and is well known as a writer in mining technology. He has been at considerable pains to present his material in that order and manner which renders it most readily assimilable by the majority of his readers. The subject is undergoing re-solution; its treatment just now is difficult, and there is evidence that the author has not found it easy to balance between obsolescent dogma on one side and the quicksands of controversy on the other. The task is too Blondin-like to escape an occasional slip. We observe, for example, a repetition of the usual fallacy in reference to the origin of the "fuel cap," as the non-luminous mantle of a flame is inappropriately called. Nor do we agree with the neglect of the "dynamic water-gauge" at the expense of the "static gauge," especially as the former is required in determining the efficiency of fans. Again, the simpler and more precise form of Pitot tube made by the Cambridge and Paul Scientific Instrument Company is to be preferred to the type illustrated, and the simpler British alternative is more satisfactory than the hygrodeik.

It is to be doubted whether the inclusion of "ventilated" colliery plans without complete analysis can be of benefit. The author has, perhaps, attempted the impossible in treating of the "ventilation of plans" in a single short chapter.

Mr. Bryson is a strong and convincing advocate of

the direct method of expressing ventilating resistance—a method which he places to the credit of Cambessédès—and for his presentation of that side of the subject we have nothing but praise.

The reputation which Messrs. Arnold have gained as the producers of well-printed and capably edited scientific text-books is not likely to be diminished by this volume, the virtues of which considerably transcend the defects.

Bibliographie de la relativité : suivie d'un appendice sur les déterminants à plus de deux dimensions, le calcul des variations, les séries trigonométriques et l'azéotropisme. Par Maurice Lecat, avec la collaboration de Mme M. Lecat-Pierlot. Pp. xii+291+47. (Bruxelles : M. Lamertin, 1924.) 90 francs.

IT is a striking instance of the acceleration of ideas in the modern world that a theory which five years ago was known only to a narrow circle of mathematicians engaged on an abstract and abstruse problem, and until then unverified, should have produced already a flood of literature. The mere catalogue of the books and articles written on the principle of relativity occupies 290 pages, and an appendix of more or less associated mathematical works, another 47. A whole century elapsed before the hypothesis of Copernicus became the universally accepted Copernican theory, and at least one generation passed before Newton's gravitation formula received general recognition. Of course in neither case was the proof so dramatic and the conviction so immediate and the interest so intense as in the eclipse expedition of 1919. The nearest analogy to that was Pascal's experiment with the barometer on the Puy de Dôme in 1648, which established the theory that the atmosphere has weight.

The author's incentive to compile this catalogue and the diligent application it required are set forth in a rather curious preface, in which the writer, a pacifist and cosmopolist, bemoans the militarism of his country and its government. The relevance is not quite clear. He tells us, however, the significant fact that numerous authors, almost all university professors, begged him with a touching insistence, that he would omit some of their writings, if not all, because they were completely false. To this request, however, he informs us he was inexorable. No doubt selection would be difficult and hazardous, but it seems hard that a writer should be held to the fatal ὃ γέγραφα, γέγραφα.

The Birds of Portugal. By William C. Tait. Pp. xii+260+10 plates. (London: H. F. and G. Witherby, 1924.) 18*s.* net.

WHEN one thinks of the many ornithologists and bird-lovers in Great Britain, and of the numerous books on British birds, it is surprising to learn that Mr. W. C. Tait knows of only one native field ornithologist in Portugal, where he has himself for long been resident, and that the literature on Portuguese birds is exceedingly meagre. His own book on the subject fills a gap in a useful way. It is almost entirely devoted to a systematic account of the status in Portugal of each species, no attempt at descriptions of birds being made. An introductory chapter describes the physical characteristics of the country. A second general chapter deals with migration, giving a somewhat disjointed but nevertheless interesting account of its Portuguese aspects. Many species which are native to Northern Europe are only winter or passage visitors to Portugal, and that country is perhaps interesting to us, ornithologically, chiefly by reason of its place in the migratory path of our own summer birds. In an appendix, Mr. Tait gives a list of all the marked birds which he knows to have been recovered in Portugal, although we notice that this is not quite so complete as it could have been made from published sources; nearly thirty species are represented in the list, in which birds marked in the British Isles and in Holland bulk most largely (little marking is done in France), although there are also birds from Germany, Denmark, Sweden, Czecho-Slovakia, and Switzerland.

Developments in Power Station Design. By E. Austin. (The Engineer Series.) Pp. xv+271. (London: Constable and Co., Ltd., 1923.) 31*s.* 6*d.* net.

THIS book will be found useful and interesting by every one connected with the design of electrical power-houses or associated with the installation and operation of steam and electrical plant. The author looks forward to the time when every factory will be driven electrically and power production will be confined to very large power stations. Before this happens, however, it is essential that every manufacturer who generates power for his private use should cut down his consumption of fuel to a minimum. This is highly desirable, not only to reduce his working expenses but also to prevent waste of the nation's coal resources.

There are excellent chapters on pulverised coal-plant, low temperature carbonisation, and waste heat. The boiler-house plant is discussed very thoroughly, but we should have liked a more thorough discussion of the electrical side of power generation. It is a pity that up to the present time very little progress has been made with the huge scheme outlined by the Coal Conservation Sub-Committee in 1918. This is partly due to the lack of interest in the subject by the nation.

Cobalt Ores. By Edward Halse. (Imperial Institute: Monographs on Mineral Resources, with special reference to the British Empire.) Pp. ix+54. (London: John Murray, 1924.) 3*s.* 6*d.* net.

THIS small work forms one of the series of Imperial Institute Monographs and follows the familiar arrangements of its predecessors, commencing with a description of the occurrences of cobalt ores and the uses to which the metal is applied, this being followed by a chapter on the sources of supply of cobalt ores within the British Empire and in foreign countries. As usual, a useful bibliography completes the volume. The work has been quite satisfactorily done, though it must be admitted that the task in this case was a tolerably easy one, as a good deal of the matter was ready to hand. The Canadian Department of Mines has published a good deal of information about cobalt, particularly the researches on the metal and its alloys by Dr. H. T. Kalmus. Naturally the statistical and other material collected by the Imperial Mineral Resources Bureau has been made use of. The little work can be recommended to any one who desires a concise review of the occurrences and distribution of the ores of cobalt.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Use of "Shear" in Geometry.

WHEN an area or solid is subjected to "shear," although the boundaries are changed in form, the area or volume remains constant.

This characteristic of shear may be applied in the demonstration of a large class of geometrical propositions, and I have found it useful in many physical inquiries.

If any plane area is supposed to be divided into straight linear elements, parallel to a given axis, and if each element is caused to move in its own direction by an amount proportional to its distance from the axis, then if the axis passes through the centre of inertia of the area, the result is a pure shear. In any other case both shear and displacement are produced, or if the axis is infinitely distant, the

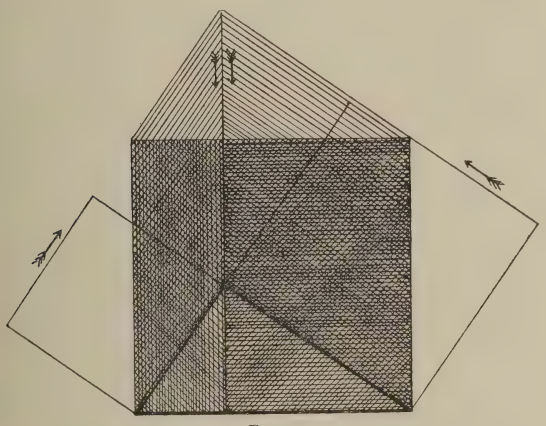

FIG. 1.

change becomes a simple displacement without distortion.

The constructions and proofs furnished by the method of shear seldom require the use of words or writing, but may be compared to the putting together of picture-puzzles in which the pieces, while retaining a constant area, may be changed in form and position according to certain rules.

The following examples will indicate the kind of propositions to which the shear method is applicable:

(1) If one side of a triangle is given, and a line parallel to that side is drawn through the vertex, then by a single shear, that is, by shifting the vertex along the line, every possible triangle can be formed which has the same base and area as the original triangle.

(2) If two sides of a triangle are given, the area of the triangle is a maximum when the angle contained by the given sides is a right angle.

(3) From this it follows that the maximum area of any polygon the sides of which are given occurs when the angles of the polygon lie on a circle;

(4) and, hence, the maximum area which can be enclosed by a line of given length is a circle.

(5) By two shears, any triangle can be converted into a rectangle of equal area.

(6) By two shears, any rectangle can be converted into an equal square.

(7) Such of Euclid's propositions as relate to equality of areas can be dealt with by shear. As an example the proof of Prop. 47, Bk. I. is shown in Fig. 1. (Here the successive pairs of shears are indicated by single and double hatching.)

(8) A circle of radius r can be converted into an ellipse with semi-axes a and b ($r^2 = ab$) by a shear the magnitude of which is $(a-b)/r$ (see Fig. 2).

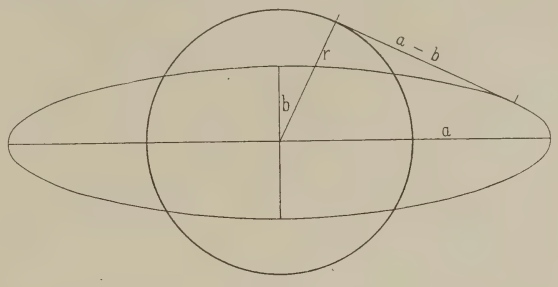

FIG. 2.

Often there are several ways of arriving at the same result, and in complex cases (especially in three dimensions) it requires some practice to select those shears which produce the required change of form with the fewest operations. It is always possible, however, by the shear method to transform any plane or solid figure into any other assigned form having the same area or volume.

June 6.

Mendelism and Evolution.

ALTHOUGH I do not wish to defend Dr. Annandale's theoretical views, or to maintain that his evidence for his conclusions was sufficient, I feel tempted to make some comments on Mr. J. S. Huxley's letter in the issue of NATURE for June 7. First, I should like to point out that Mr. Dover was using an unfortunate expression in writing that "some inherited characters at least are persistent." It is generally agreed that all inherited characters are more or less persistent. It would seem that Mr. Dover meant that some effects of environment are inherited.

Mr. Huxley states that no biologist disputes that "the differences seen between species, genera, etc. . . . stand in some intimate relation with their environment." The proposition is disputed by myself for one, and by Mr. Bateson for another, and Mr. Huxley will admit that Mr. Bateson at least is a biologist. It is necessary for "progress in evolutionary biology" to distinguish between those characters which are obviously in relation to the environment, and those which, although diagnostic of species, genera, etc., exhibit no such relation. There is no evidence concerning the majority of specific characters that they are in intimate relation with the environment.

Mr. Huxley considers that experiment is the one thing necessary for the elucidation of evolutionary problems, but I have long ago come to the conclusion that experiment by itself is of no more value than observation by itself. Two other things are essential —(1) a real and thorough understanding of the phenomena to be explained and the problems they present, (2) sound reasoning applied both to observation and experiment.

Instances are almost daily afforded of unsound reasoning from experiments, leading to erroneous conclusions applied to problems which are imperfectly understood. For example, Prof. T. H. Morgan discovered that castration of hen-feathered cocks was

followed by the development of normal cock-feathering, and drew the conclusion that secondary sexual characters were, or might be, the by-products of internal secretions the real "utility" of which was quite different. J. T. CUNNINGHAM.

University of London Club,
21 Gower Street, W.C.1.

MR. HUXLEY seems to have missed (NATURE, June 7) the main point I wished to emphasise, namely, that while criticism of one investigator's views by another is always valuable, it is stretching the point to attempt to define the grounds on which an opinion may be advanced. It is natural for a man who has studied a group of phenomena from a certain viewpoint to formulate an opinion as the result of his studies. If the admitted limitations of a paper were appreciated, together with the difficulties under which some zoologists work, I imagine they would be free from the type of criticism under discussion. That Dr. Annandale's opinions may have been strengthened or modified by experimental data I do not deny, and if Mr. Huxley's letter directs attention to the neglect of experimental work in India it will have served a useful purpose; but, as I said, it is expecting too much to require a man already engaged in studies so diverse as Dr. Annandale's to supply the need himself.

Mr. Huxley's assumption of my lack of knowledge of his studies on the courtship of birds is perhaps natural. I may mention, however, that I have always followed his writings with interest, and I ask his indulgence if I missed the ecological importance of the paper he refers to, and previously regarded it as a valuable contribution to bird "behaviour," or rather psychology.

With reference to Mr. Huxley's concluding epigram I would point out that, apart from the limited scope of Dr. Annandale's paper, attempting as it did only correlation, it seems to be inconsistent with recent opinions on the notion of cause. Mr. Bertrand Russell ("Mysticism and Logic and other Essays," pp. 180-208: London, 1919) regards the word "cause" as "so inextricably bound up with misleading associations as to make its complete extrusion from the philosophical vocabulary desirable," and if I interpret him aright he proves that the idea of causation (absent in advanced sciences) as a fundamental axiom of science is erroneous, and that the supposed "causation" is really correlation. Accepting this argument, the geneticist is also correlating, though in a manner quite different from the methods of the pure ecologist. CEDRIC DOVER.

London, June 12.

Frequency Curves of Genera and Species.

IN NATURE for June 7, Mr. Tate Regan refers to "the series x, $x/2$, $x/3$, $x/4$, etc. . . . x/x, representing the number of genera with 1, 2, 3, 4, etc. species in a group where the sizes of genera are purely a matter of chance." I am unable to attach any *definite* meaning to the phrase "are purely a matter of chance," since the sizes might be "a matter of chance" in many different ways, and I do not see what process Mr. Tate Regan has supposed to be followed. Will he be so good as to state exactly in what way he supposes the systematist to operate, and to show how the series in question arises from his operations?

G. UDNY YULE.

St. John's College, Cambridge,
June 10.

THE simple graph published in NATURE of June 7, p. 822, by Mr. Tate Regan demonstrates the result of log plotting $xy=n$, but is otherwise irrelevant. For if the matter were so simple as that, then an infinity of species per genus would be as probable as an infinite number of monotype genera, and there would be no room on the earth for us. The introductory chapter of Mr. Udny Yule's remarkable paper in the Philosophical Transactions is carefully written for the non-mathematical biologist, and should be read by all such. W. LAURENCE BALLS.

The Orchard House, Bollington Cross,
Near Macclesfield,
June 18.

Study of Explosions.

WHETHER anything physical and instructive about the atmosphere can be learnt from a study of purposely produced explosions, I am not sure. Ordinary explosives must waste much of their energy on the earth; and if atmospheric waves are wanted, it would seem better to explode a balloon filled with a detonating gas, say a mixture of hydrogen and oxygen, at a considerable height. Gas exploded without any rigid envelope, as in a soap-bubble, makes a tremendous noise, since the energy is wholly expended on the atmosphere. OLIVER LODGE.

Ball Lightning.

HAVING read the article on Ball Lightning by Dr. Simpson in NATURE of May 10, p. 677, I thought the following account of what I once witnessed, and believe to have been ball lightning, might prove of interest to some of your readers.

In August 1900 I was staying at the Voxli Hotel, Hankelid Fjeld, Telemarken, Norway. The hotel is 776 metres above sea-level and not far from the Hankelid Pass (1123 metres). On August 21 there was a terrific thunderstorm, towards the end of which I saw the particular lightning flash which I think must have been ball lightning. I will quote the actual words in which I attempted to describe the occurrence at the time.

"We were sitting in the dining-room at supper (precisely 8 o'clock Norwegian time); on an ordinary day it would still have been good daylight, but owing to the storm it was only just light enough to see the outline of the hills on the opposite side of the lake. This was the direction (south-west) from which the storm was coming, and I had been watching the particularly vivid lightning for some time, when suddenly I saw a streak of 'yellow,' apparently about one inch broad, dart from the sky just above the top of the hill opposite and, gradually falling, make straight for where I was sitting. I was too spell-bound to move, and the length of time of the whole occurrence was too short to call the attention of those who were sitting with me. I remember having the sensation that it must hit my forehead, when just as it got in front of the hotel window it changed to a ball of dazzling yellow fire (about the size of a cricket-ball) and then burst with a frightful crash, emitting volumes of violet-coloured flame, which spread in all directions. This must have happened in one or two seconds, but for several minutes afterwards I was completely dazed.

"Next day I examined the ground and found the track of the flash commenced just 20 metres (no yard measure to be had here) from the hotel window. The whole of the surrounding space is covered with small sods and branches of trees, and two or three small trees are uprooted. The most noticeable thing is a

furrow in the ground, in plan shaped like a horse shoe, but curved at both ends. Its entire length is 44 metres: its breadth varies from 7 to 24 centimetres and its depth 4 to 12 centimetres. In the path of the furrow is a large granite boulder from which two respectable-sized lumps have been cut off; one I could just lift, the other (thrown 5 metres from the boulder) I could just move but could not lift. The furrow then skirts round the edge of the boulder for a long distance, in places being completely underground. It becomes visible again farther on, passing under the roots of a small shrub, and shortly after meets the face of another rock 3 metres high. The discharge must have passed up this face, for it has left a track on the top of the rock, where moss has been torn off; but just beyond the bare rock falls into the lake and nothing more is visible."

I have some "snap-shot" photographs of parts of the track of the furrow; they are not large enough to show much detail, but I shall be glad to forward them for inspection to any one interested.

The Spiders of the Madeira Islands.

WHEN in the Madeira Islands a few years ago I collected some spiders, which have now been kindly determined by Dr. N. Banks. Although the collection is small and relatively unimportant, it suggests some problems of general interest. At and about Funchal, Madeira, I obtained *Cyrtophora citricola* Forsk., *Epeira crucifera* Lucas, *Mangora acalypha* Walck., *Teutana grossa* Koch, *Lepthyphantes tenuis* Blk., *Xysticus insulanus* Thor., *Clubiona decora* Blk., and *Chiracanthium albidulum* Blk. In the island of Porto Santo I collected *Lycosa maderiana* Walck. (abundant under stones), *Pholcus phalangioides* Fuessl. (in an outhouse), *Argiope trifasciata* Forsk. (this African species also abounds in Madeira), *Ariadne portosancti* Kulcz., *Dysdera crocata* Koch, *Dictyna* (*Ergatis*) *puella* Sim., *Epeira crucifera* Lucas, *Ero aphana* Walck., *Xysticus insulanus* Thor., *Thanatus vulgaris* Sim., *Teutana grossa* Koch, and *Zilla x-notata* Clerck.

The spiders of Madeira have been discussed by several authors, comparatively recent papers being those of Warburton (1892), Van Hasselt (1891), Bösenberg (1895), Schmitz (1895) and Kulcznski (1899). I have not seen Kulcznski's account of the Schmitz collection, though I saw the spiders themselves in the Seminario at Funchal. Warburton lists the 64 species then known from the Madeiras, 35 being supposedly endemic. As the islands are of the oceanic type, a careful study of the spider fauna should give interesting results. The means by which spiders might reach the islands are probably four: (1) Young spiders on gossamer threads floating through the air, (2) introduction by man, (3) on the plumage of birds, (4) on floating objects. The first two may be presumed to be far the most important. Such forms as the Argiope and Pholcus may be safely put down as introduced. *Epeira crucifera* seems to be a recent introduction; it is not mentioned (at least under that name) by Warburton. It would be interesting to determine whether the species likely to be carried on gossamer threads are prevalent in the islands, and whether some species frequently so carried are absent.

The differences between the spider fauna of Madeira and that of Porto Santo have not been clearly made out, and it is not known whether there are any special forms on the islets off Porto Santo. According to J. Y. Johnson (1863) there are three species of the large snail-eating wolf-spiders, *Lycosa maderiana* confined to Porto Santo, *L. blackwallii* Johns. to Madeira, and *L. ingens* Blk. to the Desertas. The snails on which they prey, representing endemic genera, are presumably much older inhabitants of the islands. Possibly there are endemic genera of spiders surviving in remote places. The collecting done so far has been mainly in the vicinity of the towns, or in the towns, and it may be that it does not fairly represent the fauna of the Madeiras. T. D. A. COCKERELL.

University of Colorado, Boulder,
May 29.

The Scotoscope.

CAN any of your readers explain the principle of the scotoscope which Pepys defines in his diary (Aug. 13, 1664) as an instrument enabling objects to be viewed "in a dark room"? It seems scarcely credible that in the seventeenth century any such instrument could have existed, and bearing in mind the lack of science which Pepys evinced, one is tempted to wonder whether he had misunderstood the instrument-maker's "camera obscura," which would account for his speaking of a "dark room" instead of saying "in darkness" or "in the dark."

Only one other reference (without definition) to the scotoscope is given in the Oxford Dictionary, and the word is generally defined in the dictionaries, through reliance on Pepys, as being what it suggests—an instrument for revealing objects in the dark. If it was merely a synonym for the camera obscura, such a definition is misleading. CHARLES E. BENHAM.

Colchester, June 18.

Chimæras Dire.

DR. FINKLER'S experiments on the transplantation of the heads of insects have attracted both scientific and popular attention to a degree which was marked on the one hand by an exhibit last year at a Royal Society soirée and, on the other, by mention in the pages of *Punch*. It is desirable, therefore, to direct attention to an emphatic repudiation of his claims which has just been published in the *Zeitschrift für wissenschaftliche Zoologie* (vol. cxxiii. pp. 157-208) by Hans Blunck and Walter Speyer.

It will be recalled that Finkler stated that the heads of adult insects could be successfully grafted on to bodies of the other sex, and even on to bodies of distinct species belonging to widely different genera. He inferred, rather than observed, the union of tissues following the operation and hastened on to describe its remarkable results, physiological and psychological. The head of an herbivorous water-beetle persuaded a carnivorous body to be content with, and seemingly to digest, a vegetable diet; a male head led a female body into unwonted perversities; and a Dytiscus strove to moderate the colouring of its wing-cases to suit the sober tastes of its new Hydrophilus brain. Experiment was added to experiment, and water-boatmen abnormally coloured by inverted illumination transferred the abnormal coloration with their heads to other individuals not so illuminated.

It was to be expected that a field of work offering such remarkable possibilities would speedily be occupied by other investigators. The living material is easy to obtain, the technique is simple ("an Roheit schwerlich zu übertreffen," say Blunck and Speyer), and the results are got in a brief space of time; and yet no one, with the solitary exception of Dr. Kammerer, appears to have claimed success in repeating even the less startling of Dr. Finkler's experiments.

Now Dr. Blunck and Dr. Speyer (already known by a long series of anatomical and biological researches

on the very water-beetles that were among the chief of Finkler's *corpora vilia*) come forward with a detailed and documented confession of their failure, after persistent attempts, to confirm the simplest of Finkler's results. They followed carefully his instructions as to procedure, and only after this failed did they try to refine upon his technique. The severed heads certainly adhered to the bodies on which they had been placed, cemented, in fact, by the coagulated blood which dried to a chitin-like hardness, but in no case did the insects survive longer than others in which, after decapitation, the wounds were stanched with a little melted wax; in no case did the chimæras behave differently from the headless trunks; in no case did stimulation of the head produce reflex movement in the body or its limbs. Microscope sections showed no attempt at regeneration or union of the tissues, but instead, a progressive necrosis, leading more or less quickly to the death, first of the head and later of the trunk. These results followed, even in cases of replantation where the severed head was replaced at once on the body from which it had been detached.

Dr. Finkler may of course be able to point out to us where the German experimenters have gone wrong, but there seems to be a familiar ring in their complaint that he has ignored requests to produce his chimæras, alive or dead, for investigation by others. He cannot ignore the challenge of their final words: "Die Wissenschaft hat angesichts der allen Erfahrungen widersprechenden Angaben des Wiener Autors keine Veranlassung, sich weiter mit ihm und seine Schriften zu beschäftigen." W. T. CALMAN.

British Museum (Natural History),
South Kensington, S.W.7.

The Origin of Ores.

REFERRING to the very kind review by Prof. H. Louis of my book "The Geology of the Metalliferous Deposits" in NATURE of June 7, p. 812, I wish to direct attention to one point. Prof. Louis quotes the following sentence: "It would perhaps be too much to say in the present state of our knowledge that all primary ore-deposits are of igneous origin, but this is a view which may very likely be established as a result of future work." He then goes on to instance the hæmatite deposits of Cumberland as ores which are certainly not of igneous origin. With this, of course, I entirely agree, and I wish to say that my statement was certainly never meant to include them, as may be seen by referring to p. 330 of my book. The emphasis in the sentence quoted is on the word *primary*, whereas I regard the hæmatites of Cumberland and northern Spain as secondary ores. Should a second edition of the book be called for, steps will be taken to make this point quite clear.

R. H. RASTALL.

Christ's College, Cambridge.

Exhibit of Pure Science at the British Empire Exhibition.

IN NATURE of June 21, p. 896, there is a reference to the instruments exhibited under my name in the Royal Society's section in the Government Pavilion at the British Empire Exhibition dealing with the measurement of atmospheric pollution. I should like to make it clear that the credit for the original idea underlying the contrast photometer exhibited is due to Mr. L. F. Richardson. It is a development of the method described by him in the Proceedings of the Royal Society, A, vol. 96, 1919. The principle was further elaborated by the Photometric Sub-Committee of the Advisory Committee on Atmospheric Pollution, my share being only that of getting out a workable design and making the experimental instrument. I was fortunate in getting at the first attempt an instrument with remarkable sensitiveness and accuracy, which required practically no alteration and enabled a measure of light obstruction by fog to be obtained.

During the smoke fog in the afternoon of November 26 last in South Kensington, a fairly dense fog containing about $2\frac{1}{4}$ milligrammes of soot per cubic metre and about 24,000 smoke particles per cubic centimetre, the obstruction of light in 50 feet was 46 per cent. In the morning of the same day at 11.45 the amount of suspended matter was 3·8 milligrammes per cubic metre and the number of particles 82,000, the obstruction of light in 50 feet being 75 per cent.

Birds as a Geological Agent.

ALL along the tops of the cliffs of the Undercliff from Ventnor to Blackgang empty shells of the common limpet are found in large numbers, and it has usually been assumed that their shape has caused them to be blown by the wind from the beach over the cliffs. There are so many of them that I have found it difficult to believe this theory, and on mentioning it to a local naturalist, he has assured me that he has seen rooks and jackdaws pick them up from off the rocks while living, and convey them in their beaks to the trees where they roost and nest and to other places, and after feeding on them, cast away the empty shells. This may account for the mixture of marine shells with land shells in some of the tertiary strata which is sometimes inexplicable.

EDWARD A. MARTIN.

South Norwood, S.E.

A Substitute for the McLeod Gauge.

THE letter on the McLeod gauge appearing in NATURE of November 3 has only just come to my notice.

There may be gauges which, having been compared with a McLeod gauge, will give equivalent readings, but there is no substitute for the McLeod gauge in its perfect measurement of low pressures, expressed in height of mercury column.

If the McLeod gauge is used with proper knowledge, it *will* indicate aqueous vapour as well as permanent gases. When the gauge is so proportioned that the difference of the height of the mercury in the capillary columns is less than 4 mm. and the temperature is above 0° C., any aqueous moisture present will act as a permanent gas and will give a true reading of the pressure absolute.

Ceremonial Banquets.

I HAVE recently received an invitation to forward a cheque for two guineas, as a fee for attending the banquet in connexion with the Kelvin Centenary. It is difficult to understand why the memory of a man of simple habits should call for such a sumptuous repast, or why scientific workers of frugal habits should be excluded from such a celebration. In view of the growing tendency to limit functions such as these to men of means rather than to men of science, it is surely time to make a protest against the methods of organisation which lead to so undesirable a result.

F.R.S.

The Plant Commonwealth and its Mode of Government.[1]

By Sir FREDERICK KEEBLE, C.B.E., F.R.S.

THE plant commonwealth lies within the contours of an individual plant — rose, lily, grass, oak tree or any other. The physical features of the commonwealth have been surveyed and are well known. Notwithstanding their differences in outward aspect, all the members of the commonwealth—root, stem, leaves, and flowers—own a common plan of organisation. As the human being is the unit of a commonwealth of nations, so is the cell or protoplast the unit of the plant commonwealth. Just as certain men have the appearance of simplicity, so has the plant cell—a minute mass of nucleated cytoplasm, bounded by a solid wall of cell-wall substance, of such small dimensions that one thousand cells might lie comfortably side by side along the diameter of a penny piece. Yet, as is the case with man, the simplicity of the cell is illusory. The cell lives, feeds, respires, grows, and does many different kinds of work. Nor does it live unto itself alone. In all its manifold activities the cell influences and is influenced by other of the well-nigh innumerable cell units of the commonwealth. Indeed, the messages which by word of mouth, by post and telephone, telegraph and wireless, pass between members of our own commonwealth and leave us but little peace, are rare by comparison with those sent and received by the living cells of plants. Throughout life they are always "listening in." In the simplest plants of all—the unicellular plants—the cell is the commonwealth. So is it in the highest (multicellular) plant at the moment of the rebirth of the individual within the ovary of the flower of the mother-plant. All plants begin life each as a single, minute mass of semi-fluid nucleated protoplasm. Every activity evinced by this living particle shows alike the diversity of its unrecognisable parts and the integrity, that is, the individuality of the whole, and throughout life diversity of activity and oneness or individuality alike persist.

From simple raw materials the cell-protoplasm restores and augments itself, and gradually stage by stage the plant carves out its body from this increasing mass of living substance. The primal cell grows and divides to form two daughter cells, each, like the mother cell, consisting of nucleated protoplasm invested by a wall or coat of cell-wall substance. Yet though a solid wall divides them, the daughter cells are not isolated from, but remain in communication with one another. For, in the first place, the separating wall is very thin and soluble substances may pass across it readily, and, in the second place, fine strands of cytoplasm radiating from the central mass penetrate into pits in the cell wall and, joining or all but joining with corresponding strands from a neighbouring protoplast, maintain vital touch between the cells. So in like manner the daughter cells divide, and the cells to which they give rise maintain vital contact by their protoplasmic connecting fibres, until after many divisions the embryo is recognisable within the swelling seed. If by some magical liquor the cell walls and all the non-living contents could be dissolved away and the transparent semi-fluid protoplasm made hard and visible, the contours of the plant would still be recognisable.

Not all of the cells which compose the body of the embryo plant remain unchanged. Some, it is true, appear to do nothing else but grow and divide. They are the producer or embryonic cells destined throughout the life of the plant to carry on the work of cell formation. Groups of them are to be found at all ages of the plant in the growing point of the root and in the buds on the stem. In long-lived plants, after a thousand years and many thousands of divisions, these embryonic cells still retain their powers of cell-formation. Theirs is the gift of perennial youth; they never grow up. Once established, a growing point exercises a dominating influence over the broods of cells which it throws off by the division of its component embryonic cells. In some way, as yet unknown, it influences or perhaps determines the morphological fate of its offspring. For, as has been shown recently, a minute fragment of a root tip $\frac{1}{25}$ in. in thickness, if cut off and fed with mineral salts and suitable proteins, grows, divides, and in the cells which it produces, the same differentiation appears as in the normal root.

Other cells of the plant body soon cease to divide, but undergo no very great change of form. They become the general working cells of the body. Others assume curious and characteristic forms and, grouped together, constitute gangs of cells—skilled cellular artisans—to each of which some special task is assigned. Yet other cells or groups of cells undergo greater change of size and shape. For example: those destined to give rise to the woody vessels along which sap passes from root to stem grow wide and very long, join above and below in single file with cells like themselves, build thick and woody longitudinal walls, often beautifully sculptured, and, losing their contents and dissolving away their cross walls, form long uninterrupted tubes—mere aqueducts. It requires but little imagination to realise how imperative must be the constraint brought to bear on those wood-forming cells to induce them thus to immolate themselves for the benefit of the plant commonwealth. Their fate suggests that as the commonwealth develops the cellular units suffer more and more curtailment of liberty. Each is constrained to endure a limitation of freedom, and each imposes a limitation on that of other units of the plant body. In this compromise between liberty and social obligation a new and higher unit is fashioned—the individual plant, that is, the plant commonwealth. If this way of regarding the individual be correct, it must be of interest to explore the nature of the messages which, passing between members of the plant body, bind them together and determine the subordination of the cells and their integration into an individual. On these trifles, "light as air but strong as iron," the existence of the commonwealth is based. It is to the origin, nature, and effects of these messages that I propose now to refer.

I know of no better way of approach to this task than by describing—at the risk of the smile it may evoke—the strange things that happen when a potato is peeled. An immediate effect of the operation is the setting up of a state of fever. During this wound fever the temperature of the tissues near the cut rises

[1] Discourse delivered at the Royal Institution on Friday, March 21.

rapidly as a result of increased cell respiration. The wounded cells die; those of the layer next to them, no longer hemmed in on all sides, find some relief from the bondage which held their activities in subjection. They grow out to form bladder-like or tubular projections. In the welter and confusion due to loss of touch with other cells, these cells break rank and become a law unto themselves. Their growth is, however, limited and aimless, and presently withering and turning brown, their dead remains form a thin dry skin over the wound. Behind the broken ranks the orderliness of behaviour of the cell layers is maintained; but it is a new order which these cells obey. They form a new front. Dividing rapidly and in a regular manner, these cells come to present the appearance of rows of microscopic bricks. When the originally single layer of dividing cells has given rise to several layers, the cells of the outermost form thick corky walls, lose their living contents, and come to consist of mere empty shells fitting as hollow bricks might fit closely one with another. Thus by the formation of wound tissue is the wound healed. Until recently, nothing was known of the provenance of the new orders which stir the cork-forming cells to activity and, releasing them from obedience to previous orders, cause these cells to renew their youth and reassume the power of division. But it is now known as a result of investigations made by Prof. Haberlandt that the renewed activity is called forth by messages from the stricken and dying cells.

The origin and nature of these messages may be determined by very simple experiments. For example: if the bulbous stem of a kohl rabi (turnip-stemmed cabbage) be cut across, all the changes just described may be observed to take place. But if the cut surface be rapidly and thoroughly washed with a stream of water, little or no cork formation occurs; the wound does not heal. When, however, the washed surface is covered with a layer of brayed-up cells of kohl rabi tissue, cork formation proceeds even more vigorously than it does in the unwashed wound. Whence it is to be concluded that messages are sent by the wounded cells and that the messages are of a chemical nature. As they die, these cells liberate some substance which, diffusing into the living cells, quickens them to activity and provokes their division. This stimulator of specific change may be spoken of as a wound hormone. Its presence may be demonstrated experimentally in many different kinds of wounded tissue, and in none better than in the succulent leaves of sempervivum and sedum. Leaves of these plants may be readily torn asunder without mechanical destruction of their cells; for the cell walls between the cells give and split so that the protoplasm of the cells remains intact. Now it may be shown that whereas by cutting a leaf and thereby destroying numerous cells the cell division provoking hormone is produced, by tearing it the hormone is not produced. The wound hormone, this message of healing, is sent out by the dying cells. Thus may plants rise by stepping-stones of their dead cells to higher things.

Further insight into the circumstances in which wound hormones are produced may be obtained by observing the effects which follow upon mechanical injury of delicate plant-tissues, as, for example, the multicellular hairs so often found on leaves and stems. These structures are formed each by the outgrowth and division of a single surface cell. This cell divides to form a row of cells placed end to end; after a few divisions growth ceases, and the constituent cells of the hair divide no more. If, however, the hairs on the leaf or stem of a coleus or zonal pelargonium be maltreated by cutting or pinching or by less drastic means, as, for example, rubbing gently between the fingers or brushing with a hair brush, cell division may in certain circumstances be resumed. If a hair be cut across with a sharp instrument the cell cut into dies at once, its contents dry up, and no division occurs in the remaining intact cells. But if the instrument, in removing the top of the hair, also bruises the cell beneath the one cut into, the bruised cell enclosed in its wall, though it dies ultimately, has time to prepare its message, and its last will and testament consists in wound hormone which, passing to the next-of-kin, endows that cell with renewed powers of cell division. The wound hormone, diffusing into a cell, exercises an attraction on the nucleus which moves up in the direction of the injury, and in consequence nuclear divisions and subsequent division occur in the part of the cell near the wall across which the hormone diffuses. In some plants, as, for example, the zonal pelargonium, the basal cell of the hair appears to resist injury more than the other cells, and hence it may happen that when the stem bearing the hairs is brushed not too harshly, all the cells of a hair are killed except the basal cell. If this sole surviving cell, though damaged as may be seen by a puckering of its wall, has not been mortally injured, it produces wound hormone and thereby stimulates itself to cell division.

It may, and I think it will be that these discoveries are destined to throw light on many obscure phenomena in plants. Thus it has long been known that by wounding a plant a turmoil may be set up which spreads from the seat of injury to the uttermost parts of the plant. When a branch of a tree is lopped there are repercussions in the roots buried deep underground. The turmoil is visible under the microscope. In normal circumstances the protoplasm of a plant cell presents no sign of movement; but in certain circumstances an incessant restlessness very marvellous to witness overcomes it. All its granular mass except the layer next the cell wall begins and continues long to circulate around the cell or else to stream up and down along certain lines. When tissues are injured this streaming or circulation of protoplasm begins in cells near the wound, infects the cells next to them, and so on until, like bees disturbed in a hive, the myriad protoplasts of the plant are all in active movement.

In the light of the experiments with wound hormones, it would seem probable that the propagation of the disturbance which leads to streaming is due to some chemical message passing by diffusion from cell to cell. Again, it would seem possible to ascribe the remarkable behaviour of the fertilised egg cell to the influence of a wound hormone. As is well known, the egg cell of a plant or animal remains quiescent until it is penetrated by the male reproductive cell. Soon after this event the fertilised cell begins actively to divide, and continues growth and division until the embryo has been formed. Ingenious experimenters

have shown that egg cells of the lower animals and of some plants may be caused to undergo division and to produce embryos even in the absence of fertilisation. Thus the unfertilised egg of a frog pricked by a needle has been caused to undergo division and development, and to give rise to fatherless tadpoles. Hence there would seem to be little doubt that, in normal fertilisation, the abrupt entrance into the egg cell of the male reproductive cell leads to the production of a wound hormone which acts specifically in provoking cell division.

It might be objected that such an hypothesis presupposes an almost incredible delicacy of protoplasmic organisation, but the objection has no weight with the plant physiologist who knows from long experience that disturbances of protoplasm, often so slight as to escape our own powers of perception, may suffice to produce marked and far-reaching effects in plants. The exposure of one side of the tip of the seedling leaf of oat or other grass to direct sunlight for periods of so brief a time as $\frac{1}{2000}$th of a second suffices to interrupt the uniformity of its upright growth and make it do obeisance to the sun. The tendril of the passion flower has a receptiveness so acute that the hanging upon it of a thread weighing no more than $\frac{1}{4000}$th of a milligram suffices to deflect the tendril from its course of growth. It curves in the direction of an incubus, the weight of which would have to be increased tenfold before we, if it were placed upon the skin, could be made aware of it by our sense of touch. The human eye is apt to distinguish small differences of light intensity. When we are young, our eyes can perceive the difference between a ninety-nine and a hundred candle-power lamp. As we grow old, acuteness of perception fails, and we are lucky if we can tell the difference between lights of one hundred and ninety-six candle-powers. A leaf can "tell the difference" between one hundred and 98·7 candle-power, so that its sensitiveness, as expressed by responsive movement, is equal to that of a fairly young eye. The trained eye is a wonderful instrument for perceiving whether or no a line be truly vertical, but I doubt whether its power is greater than that of the root of any plant. More than once a delicate experiment in plant behaviour has come to grief because the experimenter failed to notice that his table was not absolutely horizontal, and in consequence his plants not vertical. The plants themselves took heed of the displacement and set to work to rectify it to the undoing of the experiment.

(*To be continued.*)

Large Crystals of Iron.

THE paper by Prof. Edwards and Mr. Pfeil presented at the May meeting of the Iron and Steel Institute on "The Production of Large Crystals by Annealing Strained Iron" has now brought iron into the rapidly growing list of metals which can be obtained in the form of very large crystals. The research follows on a preliminary paper presented to the Institute by the same authors a year ago, in which they dealt with the commercial importance of coarse crystallisation in a number of defective stampings which had come into their possession. Methods of producing large metallic crystals may be classified under the following heads: (1) By slow cooling of the melt; (2) by drawing a rod slowly out of the melt; (3) by straining to a critical amount a test-piece composed of small metallic crystals, followed by heat treatment; (4) by the simultaneous application of strain and heat treatment to a metal wire. The method adopted by the authors is No. 3, which was introduced in 1921 by Carpenter and Elam in the case of the metal aluminium, and the large crystals produced are very similar in form.

It could have been predicted that iron would be more difficult to prepare by this method in the form of "single crystal" test-pieces than aluminium, for two reasons: (1) That no suitable form of commercial iron exists; and (2) that no heat treatment can be carried out above 900° C. on account of the A_3 change point at which the α to γ change occurs. Another difficulty presented itself in the course of the research to which reference will be made. The authors employed as their starting material mild steel plate 0·125 in. thick, containing 0·10 to 0·13 per cent. of carbon and the usual amounts of commercial impurities. The sheets were covered with a thin layer of scale which had to be removed by pickling in dilute sulphuric acid, leaving a dull metallic surface free from serious defects. The test-pieces used were from 8 to 12 in. in length by 1 to 2 in. in width. Chappell's earlier work having shown that the presence of carbon in iron restricts the size of the crystals which could be developed, and the authors' investigations of the defective stampings having shown that coarse crystallisation was more pronounced where decarburisation has occurred, it was decided to remove all carbon from the test-pieces before attempting to produce large crystals. It was necessary to determine carefully the conditions of decarburisation, since the problem resolved itself into obtaining an iron of suitable crystal size free from carbon. As the result of a large number of experiments, it was found that a grain size of approximately 120 grains per square millimetre is required. This was obtained by decarburising at a temperature of 950° C. for 48 hours (*i.e.* in the γ range), followed by slow annealing (12 hours from 950° to 100° C.). The complete removal of carbon was found to be necessary. From this material large crystal test-pieces could be prepared by an elongation of 3·25 per cent. produced by tensile stress, followed by annealing just below the A_3 change point (about 880° C.) for three days. The maximum size obtained was 4 in. × 1¼ in. × ⅛ in.

A complication from which aluminium is free is the presence of a surface film of very fine crystals which masks the very large crystals produced, and in order to reveal them it is necessary to remove this layer. The authors' experiments show that in general this film was just one crystal thick, and they concluded that those crystals in the original material which had a "free boundary" did not undergo the same kind of change during deformation by tensile strain as the interior crystals. They found, however, that if the elongation was produced by rolling, the surface film of fine crystals was not produced after annealing.

Tensile tests were carried out on test-pieces cut from strips containing large crystals, so that the parallel portion in each case was occupied by a single crystal. Values of from 9 to 10 tons per square inch ultimate stress and 30-50 per cent. elongation on 2 inches were obtained, and may be compared with about 19 tons per square inch and 53 per cent. elongation obtained for the same material in the fine-grained condition. A single crystal cut from the coarsely crystalline strip can be rolled out to 100 times its original length and reduced from 0·125 to 0·001 in. without annealing and without showing any signs of cracking at the edges. The properties in this respect were very similar to those of the aluminium crystals made and tested by Carpenter and Elam. It was found, however, that in certain circumstances these large iron crystals were exceedingly brittle, a property not hitherto observed with aluminium. If a crystal were placed in a vice in a certain way and given a sharp blow with a hammer, fracture frequently occurred along what appeared to be a cleavage plane. A large number of crystals were broken in this way. Only in a few cases did bending occur, such as would happen in finely crystalline iron. In the large majority of crystals tested it was found possible to obtain fractures in two planes exactly at right angles. The authors consider it probable that the large crystals grown in strained iron possess a similar orientation.

Messrs. Edwards and Pfeil have established two important facts which bear on the production of large iron crystals: (1) The critical strain required to produce very large crystal-growth on subsequent annealing varies with the initial grain size of the material used, the larger the grain size the greater being the strain required. With very large crystals, sufficient strain to cause growth cannot be applied, since recrystallisation occurs at the crystal boundaries. (2) Surface crystals of the original finely crystalline aggregate behave differently from those in the interior and require a greater tensile strain before they will disappear.

The authors explain these facts in the following way. In the case of a single crystal it is considered that deformation occurs by a process of slip causing little change in the crystal lattice. Some change must occur, for single crystals of tungsten, aluminium, and iron are hardened by cold work, but in the case of single iron crystals, whatever change up to 25 per cent. elongation occurs is removed on annealing without producing recrystallisation. If, however, two crystals in contact are deformed, there will be interference with slip, owing to the change in the direction of the slip planes in passing from one crystal to the other. In these circumstances some other kind of movement must occur during deformation. X-ray analysis does not indicate any difference between the lattice constants of cold worked and annealed metals, but shows a relation in the former between the direction of the crystallographic axes and that of straining.

The second type of deformation is interpreted therefore as a rotation of the crystallographic axes accompanied by elastic strain. The depth to which this change penetrates from the boundaries depends upon the degree of deformation. With small crystals but little deformation will cause the depth to correspond with the radius of the crystals. The larger the crystals the greater the deformation necessary to cause the change to reach the centres. When this second type of deformation has penetrated to the centres (and the strain at the crystal boundaries has not exceeded a certain value) the authors consider that the degree of axial alignment due to rotation has proceeded to such an extent that, on annealing, it is easier for the atoms to form a single crystal than to revert to their original orientations. With very large crystals, however, before the second type of deformation has penetrated to the centres, the strain set up at and near the crystal boundaries has become so great that, on annealing, the atoms in these highly strained regions preferably form new crystals, *i.e.* recrystallise.

With regard to the small surface crystals, the authors consider that a greater degree of deformation produced by tensile stress is required before the change is sufficiently complete to permit of growth or absorption during annealing. When, however, the critical degree of strain is caused by rolling and the freedom of the surface crystals is thus at least partly removed, their growth or absorption can occur.

Immigrant Cultures in Egypt.

By Sir FLINDERS PETRIE, F.R.S.

A GENERATION ago our view of Egypt was limited to three brilliant periods, without beginnings or connexions. The discovery of the predynastic ages in 1895 showed two successive civilisations, waxing and waning, which were disentangled by the classification of sequence-dating, and appear to have come in first from the west and then from the east. The further discovery of the royal tombs of the earliest dynasties at Abydos provided a monumental basis for what had, so far, only been recorded history. There the position has rested for twenty years, but recently much more has come to light, consolidating the long view of the past.

On a jasper cylinder seal of Asiatic work, the figure of a king named Khandy was identified with the same name recorded in the VIIIth dynasty of Egypt. As that king is shown receiving homage from a Syrian, and secondarily from an Egyptian, it appears that he was ruling in Syria and holding Egypt. Other foreign names in that dynasty indicate that the VIIth and VIIIth dynasties, who succeeded the first pyramid age, were Syrian rulers. This accords with the frequent use then of button badges, always of foreign work, and bearing designs known in Babylonia and Cilicia. Excavation of the cemetery of the IXth and Xth dynasties capital, Herakleopolis, showed an entire absence of the Syrian buttons, and a throw-back on to Egyptian lines, apparently due to a Libyan immigration.

Last winter the study of the rock tombs of the Uah-ka princes of Qau—south of Assyut—of the IXth and Xth dynasties, has opened a fresh view. It had already been noted that certain black granite sphinxes from Upper Egypt, which resembled the kings of the XIIth dynasty, were markedly of the Galla type. At

Qau, the temple-tombs cut in the rock are of exactly the plan of the Nubian temples, a form unknown elsewhere; and, further, the family name—Senusert—of the XIIth dynasty appears. These facts link together and agree with the Egyptian "prophecy" of the XIIth dynasty, that a king Ameny (=Amenemhat) should arise from the south, the son of a Nubian woman. It appears, then, that when the Syrians broke in on the north, the Gallas pushed down from the south, controlled the artists in black granite, and founded a rule of the south which centred at Qau; this was in alliance with the Herakleopolite dynasties, and eventually founded the XIIth dynasty at Thebes.

Last year there came to light some work of a prehistoric culture, differing in all respects from the recognised prehistoric Egyptian. This year the clearance of a stratified deposit showed that this unknown culture was as old, or older, than the early prehistoric age already recognised. As the known prehistoric culture is quite continuous on all sites, and bears nothing like the new material, the presumption is that we are handling remains of a still earlier period. This new culture is identical in the types of flint chipping with the flints so widely spread from the Fayum up to the Palestine desert. We have now certainly the general products of this people, who have as yet only been known by their flint work. Further, this work is closely like that of the lowest stages of Susa, and the Solutrean of Europe. All of these seem to be due to various waves of one Asiatic culture, and thus accord with the recent views in the "Cambridge Ancient History." The peculiarities of this earliest known culture in Egypt are: in flint, the swallow-tail arrowhead, delicate *vesica* tools pointed at both ends; in pottery, the thinnest and hardest ware known, polished black, with the surface streaked by comb-dressing all over; in beads, glazed steatite, garnet, and carnelian; in painting, the use of long rectangular palettes, concave at the ends, with green malachite, and red hæmatite face-paint. All of these may be seen in the exhibition of the British School in Egypt at University College, Gower Street, open on July 5-26. There will also be shown more remains of the earliest human period known in Egypt, from the gravels of the eastern desert; after further study, it is hoped to give some account of these.

Obituary.

CHARLES OBERTHÜR.

BY the death, at the age of seventy-eight, at Rennes of the veteran naturalist, Charles Oberthür, workers in the study of insect life have suffered the loss of one whom personal tastes, the circumstances of life, and a persevering and enthusiastic character combined to make a conspicuous and leading figure among the fraternity of entomologists. As the printer and producer of his own works, Oberthür was able to give full scope to his conception of the requirements of entomological description and illustration. Similar ideals have presented themselves to others, but to few indeed has the opportunity been given to carry them out on so extensive and magnificent a scale. The splendid series of "Études d'Entomologie" and of "Lépidoptérologie Comparée" which emanated from his press at Rennes bear witness to his indefatigable labours in the advancement of his favourite pursuit, and to the liberal, one might even say the lavish, expenditure which he devoted to the worthy presentation of the results of his entomological studies. The beauty and accuracy of the hand-painted illustrations in these volumes have never been surpassed.

Though the order of Lepidoptera engaged most of his attention, Oberthür did much to further the subject of economic entomology, which he rightly recognised as being of high importance to an agricultural community such as that of the greater part of France. The material accumulated by him is of the greatest service to students of bionomics; but to Oberthür himself the various topics offered by evolutionary problems, such as those of protective resemblance, mimicry, phylogeny and distribution, made little or no appeal; nor did he concern himself with experimental investigation of the phenomena of heredity. But in his own line, and in the working out of his own methods, he was exceptionally efficient. Many have had occasion to be grateful for his kindly and helpful generosity.

PROF. FILIP POČTA.

WITHIN the past few months death has taken heavy toll among the professors of the Charles' (Bohemian) University of Prague. On January 7 died Prof. Počta, professor of palæontology and geology. He was born in Prague in 1859 and studied first in our University, then in Bonn, in the Musée d'Histoire naturelle in Paris, in the Lavalle Museum in France, and from there in Stockholm with Prof. Lindström. His first big work was a modern investigation of the sponges from the Bohemian calcareous formation, of which he studied not only the external form but also the interior skeleton, and this study he extended to sponges from Hungary, Dresden, France, and from the collection of the Bonn University. After this he studied the rudists and worked in the Sorbonne, the École de Mines in Paris, as well as in the British Museum. After the death of Prof. Novák he investigated the material which was left by Barrande, who intended to describe it in the eighth volume of his classical work, "Système silurien du centre de la Bohême." For this purpose Počta made a great collection of illustrations of corals and Cœlenterata, a collection which was, as regards execution, without a rival. He also deciphered for the first time the inner structure of the end chamber of Orthoceras. The first part of the eighth volume was published in 1894 and the second in 1902. Being originally a palæontologist, he became later on a geologist. He published much in both sciences in Bohemian, German, French, and Magyár. Počta was a member of the Royal Society of Bohemia, of the Bohemian Academy of Sciences, of the Geological Societies of Paris, Berlin, and of other learned societies. BOHUSLAV BRAUNER.

WE regret to announce the following deaths:

Dr. George Little, state geologist of Mississippi, 1868–72, and of Georgia, 1874–81, on May 15, aged eighty-six.

Prof. Charles Hunter Stewart, professor of public health, University of Edinburgh, on June 30, aged sixty-nine.

Current Topics and Events.

THE history of the discovery of insulin occupies an almost unique place in the scientific literature of recent times, and in the supplement which accompanies this issue we print an account of the present position of investigations regarding this substance. So many investigators had previously been within an ace of making its discovery that, as Prof. MacLean says, "it still remains a mystery why insulin was not isolated many years ago." The discovery is a good illustration of two salient facts bearing on scientific research work: first, that a very slight modification of a technique which had led previous explorers to failure might lead one to success; secondly, that research work of an applied nature, such as the search for a cure for diabetes, is very closely dependent upon related investigations which belong more properly to the domain of academic science—in this instance the improvement of methods for the accurate determination of small quantities of glucose in the blood. Insulin as now placed on the market is a therapeutically trustworthy preparation, and there must be many persons who owe life and health to the careful administration of this substance. But we must not be too sanguine that a diabetic taking insulin is to be regarded as a normal person. Prof. MacLean's article also contains a warning which it is to be hoped will be taken seriously to heart: careful investigation has shown that no beneficial results ensue from taking any pancreas preparation by the mouth, and this also applies to insulin itself, which is speedily destroyed by the juices present in the alimentary canal. From the academic point of view, insulin presents many problems of absorbing interest. At present the chief of these is the problem of what happens to the blood sugar and to glycogen after the administration of insulin: both apparently disappear, yet no intermediary or end products have yet been traced. Lastly, it cannot be too strongly emphasised that the discovery, from start to finish, could not have been made without those experiments on living dogs which some would seek to have abolished.

WHY it should have been left to Sir Douglas McGarel Hogg, Sir William Bull, and Sir Malcolm Macnachten to bring in "a Bill to confer certain powers on the Trustees of the British Museum," we have been unable to ascertain; nor can we discover whether the idea arose in the minds of those gentlemen spontaneously, or whether the seed was sown by some such body as the Museums Association. The Bill is, in brief, to empower the Trustees, under certain conditions, to lend for public exhibition in any gallery or museum controlled by a public authority in Great Britain, specimens falling under the graphic arts, jewelry, and "objects of art in gold, silver, bronze or crystal,"—a sufficiently curious selection. It proposes, therefore, an extension of the openings already made in the foundation Act of 26 George II., by which all objects entering the Museum were to "remain . . . to all Posterity." The Trustees have already obtained power to exchange, sell, or dispose of (7 & 47 George III.), as also to give away (41 & 42 Vict.), duplicate objects "not required for the purposes of the Museum"; but they have not as yet the power to lend. We do not know that they want it. If they are given it, we may rely on them to exercise it with due discretion. The British Museum is a storehouse to which there come by thousands inquirers from the uttermost ends of the earth. Such a student must not arrive in London to find that, of the objects he wishes to compare, one has been sent to Aberdeen and another to Penzance. There can never be any advantage in encouraging the British Museum to emulate the admirable Circulating Department of the Victoria and Albert Museum.

IN the *Times* of June 26 there was a somewhat sensational paragraph entitled "New anti-tuberculosis vaccine." It was stated that Prof. Calmette of the Pasteur Institute had, with various collaborators, discovered a new tuberculosis preventive. The further contents of the paragraph show that in its essence the discovery is not altogether new and has in part, at any rate, been referred to on more than one occasion, and most recently in the Annales de l'Institut Pasteur (xxxviii., 1924, p. 371). Calmette's vaccine is a living culture of tubercle bacilli which has been grown on a potato medium containing bile and glycerin for thirteen years. During this period it has become avirulent and is incapable of producing tuberculosis. It is claimed, however, that it is capable of establishing an immunity against virulent tubercle bacilli, and particularly so when injected into calves shortly after birth. The protection afforded by the avirulent bacilli lasts for more than a year. It is believed that the same results may be obtained in infants, and some work in this direction is briefly referred to in the *Times* paragraph.

IN NATURE of May 10, p. 685, we published a note on the alleged discovery of the long-sought virus of foot-and-mouth disease by Profs. Frosch and Dahmen of Berlin. From the reputation of these workers and their statement of experiments we were inclined to regard the discovery as correct, and this now appears to be so. In an article in the *Lancet* of June 28 considerable details are given of a lecture delivered by Dahmen and Frosch at Utrecht, and it is therein stated that a committee of six experts, including such well-known investigators as Titze, Giese, Kleine, and Gins, have been able to confirm the statements of Frosch and Dahmen, and that with subcultures of the virus in the sixth and twenty-sixth generation they had succeeded in reproducing the disease. On the assumption that the virus of foot-and-mouth disease has been discovered, it has been assumed by some that a royal road has been opened up for the prevention of the disease, but it is perhaps scarcely necessary to point out that this is not a corollary, for the establishment of immunity may not take place in spite of the presence of the virus.

THE annual conversazione of the Institution of Electrical Engineers held at the Natural History Museum, South Kensington, on Thursday, June 26,

was one of the most notable of a long series of annual functions in pleasant surroundings, due to the fact that it was held on the hundredth anniversary of the birth of Lord Kelvin, and formed a part of the group of centenary celebrations being held this summer in scientific and engineering circles, and to include, as we have already announced, the Kelvin Centenary Oration by Sir J. J. Thomson on July 10 and the Kelvin Centenary Banquet on the following day. A large company was received by the president, Dr. Alexander Russell, and Mrs. Russell and members of the Council of the Institution, and an excellent programme of vocal and instrumental music, in which Miss Phyllis Carey Foster took part, was provided in the Reptile Gallery, while the string band of the Royal Engineers performed in the Central Hall. Many distinguished engineers were present, and there must have been many there who remembered Lord Kelvin's regular attendance at these conversaziones in his later years.

IT is of interest at the present time to recall that Lord Kelvin, Sir George Stokes, and Prof. Huxley were elected fellows of the Royal Society in the same year and on the same day, namely, June 5, 1851. Each of this brilliant triumvirate lived to receive the honour of the presidency, in 1883, 1885, and 1890 respectively. The certificate of candidature of Lord Kelvin (William Thomson) was signed by Michael Faraday, John Couch Adams, and Adam Sedgwick, the distinguished Woodwardian professor of geology in the University of Cambridge. In retrospect, the support of Sedgwick is especially interesting since we know, through Sir Archibald Geikie, that from the year 1844 onwards for some eighteen years Lord Kelvin watched with increasing impatience the spread of the doctrines of the Uniformitarian School in geology, and at length, in 1862, "broke silence on the subject, declaring the doctrines of that school to be opposed to physical laws." It was one of the accepted tenets of the Uniformitarian School that the range of past time available for the explanation of the phenomena of geology was unlimited; but by arguments drawn from the origin and age of the sun's heat, the internal heat and rate of cooling of the earth, and the tidal retardation of the earth's rotation, Lord Kelvin fixed limits to the possible age of our planet. These have, of course, more recently been disputed. Lord Kelvin was always most punctilious in correspondence. Following the onerous engagements incidental to the celebration of his professional jubilee at Glasgow in 1896, he occupied himself on the way to London in writing autograph acknowledgments of the congratulation of friends. Not a few of his distinctive shorter papers were composed during railway journeys between Glasgow and London. In fact, wherever there was motion he found an atmosphere of calm, the hum of machinery acting as a mental stimulus. Mention may be made here that Lord Kelvin's portrait, by Orchardson, hangs in the Royal Society's meeting-room, the gift of a circle of fellows.

A TORNADO of hurricane strength swept over a fifty-mile stretch of the southern shore of Lake Erie in the afternoon of Saturday, June 28. According to the correspondent of the *Times*, three hundred persons are believed to have perished at Lorain, and the number of persons injured in the devastated track is estimated to be 2500. Many buildings are completely wrecked at Lorain, and in parts of the town it is reported that not a house was left standing. The principal destruction and damage occurred between Sandusky and Cleveland, and fear is entertained for some small passenger steamers plying on the Lake. The report states that the full extent of the damage will not be known for days. Earlier in the day, much havoc is said to have been caused by storms in the Upper Mississippi Valley. At Peoria, Illinois, hundreds of houses were unroofed and damage is reported from other places. The U.S. Weather Bureau will without doubt give details of the tornado. In the past, many such storms have been dealt with, notably by Finley and Ferrel.

IN view of some criticisms that have been made in Canada concerning Dr. V. Stefansson's recent geographical discoveries in the Arctic, attention may be directed to an article in the *Geographical Journal* for June. The Royal Geographical Society, on receiving from Mr. J. White, technical adviser to the Ministry of Justice, a detailed statement of the criticisms, submitted these to a searching examination by an impartial authority. All relevant original documents were consulted, including blue books of the various Franklin search expeditions, Sverdrup's charts of the adjoining regions, and Dr. Stefansson's own charts. A lengthy reply to Mr. White's letter, illustrated with charts, is published. Each point is examined in great detail, and the conclusions reached may be taken as final. They completely exonerate Dr. Stefansson of the charges that his discoveries of new land were anticipated by previous explorers, with the sole exception that Lougheed Island may have been sighted by Richards in 1853, but there was no suggestion of a land mass of the size of the island charted by Dr. Stefansson. The extensive islands now called Brock and Borden Islands were never suspected to exist. The Royal Geographical Society has done a service to polar exploration in disposing of these criticisms and establishing the validity of Dr. Stefansson's claims.

IN our issue of June 16, 1923, p. 818, reference was made to the formation of a committee to collect funds in order to commemorate the late Prof. A. D. Waller and Mrs. Waller. We understand that the fund has now reached a total of 1820*l.* and that a meeting of subscribers, probably a final one, will be held on July 5 at 5 P.M. at the London (R.F.H.) School of Medicine for Women. It will be remembered that the fund is to be used for the promotion of scientific research and is to be administered by the council of the London (R.F.H.) School of Medicine, with which Prof. Waller and Mrs. Waller were associated for many years. It is hoped that the fund will reach 2000*l.* by the time of the meeting on July 5, and that it will then be possible to discuss the final form of the memorial.

THE staff of the Bombay Department of Agriculture interested in research into botanical and genetical problems has grown very considerably of recent years, and on April 14-16 the plant breeders of the Department held a conference in the Botanical Laboratories of the College of Agriculture, Poona, under the presidency of Dr. W. Burns, Economic Botanist to the Government of Bombay. An introductory address by Dr. H. H. Mann emphasised the need of attacking problems of economic interest in a truly scientific manner, and the subsequent proceedings of the conference, when methods of testing the performance of varieties of crop plants of economic importance were rigorously examined in the light of modern knowledge of statistical, botanical, and agricultural technique, suggest that Dr. Mann was preaching to the converted. Some forty specialists gathered at the conference, which was convened at short notice; they were drawn from the fifteen workers in the Government Plant-breeding Department, the five men working under the Sassoon David Trust, the Indian Cotton Committee investigators, and the staffs of the Economic Botanist and the Horticulturist. The conference also utilised the occasion to examine the experimental and demonstration plots conducted by the Poona College of Agriculture, of which Dr. Burns is Principal. At the close the conference recommended to the Director of Agriculture that such a conference should be held annually, and that next year it should meet in Surat.

THE influence of Joseph Leidy on science forms the subject of three interesting addresses delivered in December last at the Academy of Natural Science of Philadelphia and published in the *Scientific Monthly*, April 1924. The veteran Dr. Edward S. Morse said that in the midst of the rush for the description of new species, Leidy pursued his researches on the habits and anatomical details of creatures ranging from the protozoa to mammals, and his profound knowledge of the osteology of mammals enabled him to lay with a master hand the foundation for the palæontology of the reptiles and mammals of North America. Nearly a third of his published memoirs, extending over a period of forty years (1848–88), are on this subject. Prof. W. B. Scott reminded his audience that Leidy throughout his life was primarily interested in human anatomy and that he remained, almost to his death, professor of human anatomy in the Medical School of the University of Pennsylvania. Prof. Scott paid generous tribute to the value of Leidy's work in palæontology and geology. He stated that Leidy was the first to show that there were native horses and rhinoceroses in America, and he also found the first American camel. Prof. H. S. Jennings pointed out that Leidy seems to have attempted and carried out to a remarkable degree of success the project of forming for himself, and communicating partly to others, a detailed picture of the living world in relation to the environment. He was the better enabled to do this because of his artistic aptitude; indeed his work is largely a portrayal of Nature as seen by a thorough scientific artist, of which his great memoir on the fresh-water rhizopods is an outstanding example.

WE learn from *Science* that Prof. J. C. McLennan, of the University of Toronto, has been elected president of the Royal Society of Canada.

THE Agricultural and Horticultural Research Station of the University of Bristol will be open to visitors on July 15, when the experimental work in progress will be demonstrated by the staff.

MR. E. E. AUSTEN has been appointed deputy keeper in the Department of Entomology of the British Museum (Natural History), South Kensington.

THE Franklin Institute of the State of Pennsylvania for the Promotion of the Mechanic Arts was incorporated on March 30, 1824. The centenary, therefore, falls due this year, and will be celebrated on September 17-19.

APPLICATIONS are invited for two assistantships at the Solar Observatory of the Commonwealth of Australia. They should be sent to reach the High Commissioner for Australia, Australia House, Strand, W.C.2, by, at latest, July 31. Further particulars are obtainable upon request.

MR. E. R. D. MACLAGAN has been appointed by the President of the Board of Education to succeed Sir Cecil Harcourt Smith, who will retire from the position of Director and Secretary of the Victoria and Albert Museum in September next. Mr. Maclagan has been deputy keeper of the Department of Architecture and Sculpture in the Museum since 1921.

THE Imperial Botanical Conference opens at the Imperial College of Science and Technology, South Kensington, on July 7, under the presidency of Sir David Prain. A large number of overseas and British botanists have signified their intention of attending the Conference, for which an attractive programme has been arranged.

THE Safety in Mines Research Board is in need of the services of a number of abstractors—men or women—able to make rapid and accurate translations (abstract or full) from German and French scientific publications. Applications for the posts, giving full particulars of qualifications, etc., should be addressed to the Under Secretary for Mines, Mines Department, Dean Stanley Street, S.W.1, not later than July 19.

A GOVERNMENT chemist is required for service in Fiji, largely in connexion with the agricultural department. Candidates should, if possible, be University graduates; they must be associates and fellows of the Institute of Chemistry, and have had experience of the work of a public analyst. Requests for forms of application and for further particulars should be addressed in writing to the Private Secretary (Appointments), Colonial Office, Downing Street, S.W.1.

A DECIMAL-METRIC Conference has been arranged by the Decimal Association and will be held on July 9 in the house of the Institution of Electrical Engineers. The subjects to be discussed are decimal coinage,

with special reference to the ten-penny shilling, and piecemeal proposals for introducing metric weights and measures. Among the speakers will be Sir Robert Horne, Sir Robert Hadfield, Sir Napier Shaw, Mr. Harold Cox, Mr. Gordon Selfridge and Mr. Felix Blakemore. A number of chambers of commerce and other public bodies in the Dominions Overseas are sending delegates, and representatives from the United States will also be present. In connexion with the Conference a visit to the National Physical Laboratory, Teddington, has been arranged for July 10.

AT a meeting of the Botanical Society of Edinburgh, to be held at the Royal Botanic Garden, Edinburgh, on July 17 and 18, demonstrations and communications on various aspects of vegetative plant propagation are to be given. At the morning sessions of the meeting, numerous illustrations of the methods and results of propagation from stem, leaf, and root, will be presented, while the afternoon sessions will be devoted to the reading of papers and to a general discussion of the exhibits. The following papers will be read: (1) The propagation of clematis, by Miss Edith Philip Smith; (2) on cuttings of camphor, by Miss Oona Reid; (3) horizontal branch propagation, and (4) root cuttings, by Mr. L. B. Stewart; (5) propagation by bulb scales, by Dr. R. J. D. Graham.

THE Egyptian Government Almanac for 1924 (Cairo: Government Publications Office, 1924; price 10 P.T.) maintains the high standard of usefulness of former editions. It contains a good deal of statistical matter, but aims rather at being explanatory and descriptive. Matters of scientific interest include some papers on the geographical features of Egypt and a useful article on the Nile, its tributaries and water supply. There are notes on the survey of Egypt, the antiquities department and the physical department, including a summary of meteorological data. The section on agriculture and industries is particularly full.

MESSRS. H. SOTHERAN AND CO., 140 Strand, W.C.2, and 43 Piccadilly, W.1, have just issued No. 789 of their "Price Current of Literature," being No. 3, Pt. 4, of their "Catalogue of Science and Technology," and comprising the titles and bibliographic details of some hundreds of books relating to physics, many of which are rare and of great interest and importance. A valuable list of works by, and respecting, Sir Isaac Newton is included. The catalogue should appeal to all students of physics.

ERRATUM.—In announcing the award of a Research Prize of 1000 dollars to Dr. Mary Evelyn Laing in NATURE of June 28, p. 935, it should have been stated that the award referred to is the Ellen Richards Research Prize for 1924.

Our Astronomical Column.

EYEPIECES USED BY SIR WILLIAM HERSCHEL.—It is well known that Sir William Herschel stated that at times he used eyepieces giving magnifying powers in the neighbourhood of 6000. The eyepieces themselves seem to have been lost sight of after his death, and considerable scepticism as to the reality of these powers was expressed by subsequent writers. But recently, Dr. W. H. Steavenson, who was making by request a thorough examination of the Herschel instruments at Slough, found the eyepieces in question, and measured their powers with a dynamometer. He found values agreeing within 10 per cent. of those stated by Herschel, the highest power being well over 6000. This was naturally a single lens, $\frac{1}{60}$ inch in diameter. From a highly enlarged photograph the lens was seen to be not a natural spherical drop, but carefully figured. The curves were hyperbolæ rather than circles, and the two sides were not quite symmetrical, but Dr. Steavenson found that he could get fair definition on a portion of Saturn: the diameter of the well-defined region was only 26″, so that it must have been excessively difficult to keep objects in the field without equatorial mounting. It is satisfactory that Sir William Herschel's accuracy of statement is once more vindicated.

MINOR PLANETS.—The observation of these bodies, which was greatly interrupted by the War, is now once more in full swing. Several interesting objects have been detected in recent months. *Astr. Nach.* No. 5293 contains a study of the special perturbations by Jupiter and Mars of 132 Aethra, by Mr. C. J. Merfield, of Melbourne Observatory. He gives osculating elements for the oppositions of 1924, 1925, 1926, together with an accurate ephemeris for the next few weeks. This body was found by Watson in 1873, and was then lost for fifty years, being recovered in December 1922.

Astr. Nach. No. 5292 contains some observations of Eros made at Berlin-Babelsberg last autumn, its magnitude being 9·6. The planet afterwards went southward, and its observation was continued at Johannesburg. Dr. Witt, its discoverer, is engaged on a careful study of its perturbations, in order to predict the conditions of its near approach to the earth in January 1931. These recent observations will be very useful, as the planet was fairly near the earth.

The last assignment of numbers to recently discovered planets extended to No. 995. As many have been discovered since, the next numbering, in a few months' time, will undoubtedly extend beyond 1000. It should be noted that the number of those known to exist, but not all observed sufficiently for definite numeration, passed 1000 several years ago.

REPORT OF THE CAPE OBSERVATORY.—Dr. H. Spencer Jones, recently appointed H.M. Astronomer at the Cape, has just issued his first annual report. Besides the usual meridian observations, heliometer comparisons of the major planets with neighbouring stars are being made regularly. These have a considerably smaller probable error than meridian places, so will ultimately be very useful for improving the tables of these bodies.

Stellar spectrographs have been taken with the Victoria telescope for the measurement of radial velocities. Many plates have also been taken for proper motions both with this telescope and the astrographic: they are examined by Dr. Innes with the blink micrometer. Messrs. Long and Skjellerup, two voluntary observers, used the small equatorials for the study of 60 variable stars, obtaining more than 140 observations.

Dr. Halm is continuing his studies on stellar masses and luminosities. He suspects that the masses are grouped round the values 6·5, 3·3, 1·6, 0·8, in terms of the sun; they appear to form a geometrical progression. Further details are promised shortly.

Wireless time-signals for the use of ships are sent from the Observatory to Slangkop, where they are automatically distributed.

Research Items.

POPULATION AND ENVIRONMENT.—Dr. S. M. Shirokogoroff has published, through Messrs. Edward Evans and Sons of Shanghai, under the title "Ethnical Unit and Milieu," a valuable study of population problems, in which he lays down a number of propositions supported by examples drawn mainly from his studies of the peoples of north-eastern Asia. In a community, if an increase of population exceeds the possibility of nourishment, the excess of population must perish or the natality must be regulated by some means, medical, artificial, social, etc. Increase of population is regulated by the extent of territory and by the growth of culture; the more intensive the exploitation of territory, the larger the population it may nourish, as, for example, in an agricultural as contrasted with a hunting community. Maintenance of the level of numerical value must be understood relatively to the variation of culture and territory, a conclusion which has a direct bearing upon the question of degeneracy and decline of any given people. Variation of some aspects of the cultural complex is followed by variation in the whole complex and entails a period of cultural disequilibrium. Physical degeneracy may be either a process of extinction or a substitution of one anthropological type for another; in both cases there is an ethnical disequilibrium. Limitations being imposed upon the possibility of variation in the factors of culture, territory and density of population, which are interdependent, the general conclusion follows that there will be a degeneration or decline and an end of the present species of man. It is probable that the greater part of the way to absolute density of population is already covered, and that mankind is at present near its culmination.

THE MOTHER GODDESS IN EGYPT.—In No. 11 of the Journal of the Manchester Egyptian and Oriental Society, Mr. John Lewis analyses certain forms of Egyptian belief with the view of showing that they point to conceptions associated with the cult of a Great Mother Goddess such as Prof. Elliot Smith has postulated to lie at the root of primitive and early religion. Mr. Lewis compares the graffiti of the rocks at Gebel Hetematt, Wady Hammanat, and Selsileh, and the paintings of the prehistoric tomb near Hierakonpolis, with the cave drawings of France and Spain, and from their similarity deduces that they are based upon identical magical ideas connected with food and protection. The statues of the god Min, at one time a female deity, link up the ideas of water, the life-giving element, the shell, which is the life-giving female deity, procreation, the mother-deity and the father-deity. The girdle of Hathor-heads on the slate palette of Narmer is a development of the shell-girdle, the strength of Hathor-Isis, which connects the shell-deity with Hathor.

ORIENTAL PREHISTORY.—M. J. de Morgan contributes to *l'Anthropologie*, t. xxxiv. 1-2, the first of a series of articles on the prehistory of Western Asia and Egypt. In neolithic times, possibly from late quaternary times, it is suggested as a working hypothesis that the areas under consideration were inhabited by four races—in the north a white Caucasic race, of which traces may perhaps still be found in the remote mountain districts of the Caucasus; in the south, stretching from Elam to the Mediterranean, a negrito race related possibly on one side to peoples living in the Indian Peninsula, on the other to the inhabitants of the European caves; in Egypt and North Africa, Berbers; and Semites in Arabia. This multiplicity of races at this stage throws no light upon the question of origins. That part of Western Asia, of which the country of the Euphrates and Tigris—the cradle of civilisation—is the centre, is cut off from the rest of the world. It contains three types of geographical areas, a mountain region, plateaus, and plains. An examination of the geological conditions from early quaternary times indicates that Chaldæa, lying between mountains and plateaus with their cold and humid climates and the hot dry desert area, alone afforded conditions suited to man in early times, and this owing to the fact that it was watered by two rivers. The plateaus did not become habitable by man until he possessed domesticated animals capable of subsisting on pasture land.

ANIMAL LIFE IN DESERTS.—In the Proceedings of the Royal Society, B, vol. 96, 1924, pp. 123-131, Mr. P. A. Buxton records the results of some investigations made in Palestine on the relations of temperature and moisture to animal life in deserts. This observer finds that the soil surface commonly reaches 60° C. at midday, and certain insects are active upon it even at that temperature. Their body temperature is lower than might be expected, probably owing to loss of water during respiration. An interesting point is that the black form of a dimorphic grasshopper has a body-temperature 4-5° higher than the buff form, when exposed to the sun. If the loss of water hypothesis be correct the insect's need for water is greater than is commonly believed. Deserts have a great diurnal range of temperature and of relative humidity. The night air is often almost or quite saturated with moisture, while by day the humidity may drop to 20 per cent. It appears that the desiccated fragments of the annual vegetation are hygroscopic: that they take up a considerable proportion of water from the moist night air and hold it for several hours after the sun has risen. The author believes that this property of the dried pieces of grass and herbage is one of the foundations which support all animal life in deserts during summer. These fragments, with the moisture absorbed over night, are eaten by certain insects which in turn become a source not only of food but also of water, for the birds, lizards, predaceous insects, and other carnivorous animals.

SYMBIOSIS BETWEEN TERMITES AND THEIR INTESTINAL PROTOZOA.—L. R. Cleveland has given further details of his work on the symbiotic relationships between the intestinal protozoa of termites and their host (*Biol. Bull.*, vol. 46, pp. 177-225, 1924). The protozoa principally concerned are flagellates—Trichonympha and related forms. By incubating termites at 36° C. for 24 hours (a method due to Grassi) the flagellates are killed, but the termites are uninjured. If such "defaunated" termites are given their normal diet of wood, they eat quantities of it, but they become less active and die within three or four weeks. If "defaunated" termites are placed with ordinary ones, the former—by feeding on the fæces of the latter—become reinfected with protozoa, and after about ten days regain the ability to utilise wood and can live indefinitely. When termites were starved, the wood-ingesting protozoa in their intestine died within eight days, and the termites when returned to a wood diet lived only a few weeks. These and other examples emphasise the close correlation between the wood-feeding habit and the presence of protozoa. That the latter use the wood as food and not the intestinal fluids of their host is

proved by direct observation—numerous wood particles are present in the posterior portion of Trichonympha—and by the fact that these protozoa die ten to twenty days before their host when wood is withheld. In normal-feeding termites a large percentage of the wood which they have eaten may be found in the protozoa, and in termites starved for a few hours it is almost impossible to find any wood particles in the intestine ; they have all been ingested by the protozoa and the particles gradually disappear. A large amount of glycogen is present in these protozoa produced by digestion of the wood. The termites furnish food and lodging to the protozoa, and the latter provide products formed by digestion of the wood—a clear case of symbiosis. The young termites feed on excreta loaded with flagellates, so that they are practically certain to become infected, and then they begin to eat wood.

MASS RELATIONS OF CYTOPLASM AND NUCLEUS.—Prof. R. W. Hegner brings together (*Scientia*, June 1924) evidence from his observations on Arcella and Opalina and from those of other investigators on protozoa, in regard to the mass relations existing between cytoplasm and chromatin, and concludes that the following generalisations are reasonably established : At each stage in the life cycle of these organisms there is a fairly definite amount of cytoplasm associated with each nucleus. The size of the nucleus is an indication of the amount of chromatin contained within it ; the amount of chromatin is the real factor involved in the ratio of nucleus to cytoplasm. Nuclear division is initiated by an increase in the amount of cytoplasm as compared with that of the nucleus.

VITALITY OF POLLEN GRAINS.—Mr. S. Nohara (*Japanese Journ. of Botany*, vol. 2, No. 1) has made an experimental study of the pollen in several species and hybrids of Salix. Germination of the pollen was most successful in 2-5 per cent. sugar solution, beginning very quickly, and the pollen tubes attaining a length of 4-8μ in half an hour. Tests of the longevity of pollen showed that it was much affected by temperature, humidity, and light, and that its germinating power could be maintained for seventy days in a dry, cool, dark place. Temperatures so low as 21° below zero for 8 hours do not lessen the germinating and fertilising power, while a temperature so high as 37° kills the pollen. Chloroform vapour terminates the germinating power of pollen in 4-5 hours, and ether vapour in 20 hours. In certain hybrids between *Salix viminalis* and *S. multinervis* the pollen and seeds were nearly normal, but the catkins showed various intersexual conditions.

BOTANICAL NOTES FROM CEYLON.—The Annals of the Royal Botanic Gardens, Peradeniya, vol. viii., May 1924, is mainly contributed by Mr. I. Petch, Government Botanist and Mycologist, Ceylon. A long paper upon the insect catching proclivities of the flowers of species of Aristolochia cultivated in Ceylon includes a record of their insect visitors so far as identification of the tropical insects had proved possible. Mr. Petch concludes that the flies are attracted to the flowers by their odour, which is offensive in *A. gigas*, but in some species, such as *A. ridicula* and *A. elegans*, is not detected by man's senses. The flies then seem to enter the tube of the flower by accident, and are prevented from crawling out by the inwardly and downwardly directed hairs, until later these hairs wither. One interesting conclusion from the record of insect visitors is that the hooded type of flower, which is regarded as primitive, is the most effective in attracting and trapping insects ; the striking bizarre forms, such as *A. ringens*, attract few flies, so that " the advantage of a further evolution in the direction taken by these extraordinary forms is not obvious." Mr. Petch also describes the species of Xylariaceæ recorded for Ceylon up to the present date (pp. 119-166), and has a note upon extraordinary forms of fructification extending the range of variation recorded for Diplodiella. Mr. C. Ragunathan confirms the occurrence of teleutospores in *Hemileia vastatrix* B. and Br., the coffee leaf disease ; they were previously recorded by the late Prof. Marshall Ward, but have not been seen by subsequent investigators.

ORIGIN OF TINSTONE.—Bulletin No. 5 of the Geological Survey of Nigeria, by Mr. C. Raeburn, deals with the tinfields of Nassarawa and Ilorin Provinces (London : Crown Agents for the Colonies, 1924. 10*s*. net.) It describes two separate areas in considerable detail and discusses the origin of the tinstone, which it says " is due to pneumatolytic action on the granite and gneisses near their contact. This gives rise to greisen, usually containing topaz and tin, and carrying networks of quartz veins with tinstone, and at times to a complete replacement of the rock in the direction of topazisation or micasisation. As regards that part of the tinstone which is related to the pegmatites, it must be emphasised that it, both in point of time and manner of origin, is quite different from the other. On the one hand we have tinstone as an original constituent which had already commenced to crystallise before the intrusion of the rock ; on the other we have tinstone as a later mineral formed by pneumatolysis after the intrusion and solidification of the granite."

ZIRCONIUM AND HAFNIUM ORES.—The results of some analyses of zirconium ores by G. Hevesy and V. T. Jantzen are published in the *Chemical News* for May 30. Malacon from Madagascar and from Hitterö is particularly rich in hafnium, the former containing so much as 7 per cent. and the latter 5 per cent. of hafnium oxide. Three out of four specimens of thorteveitite showed a higher hafnium than zirconium content. The superior radioactivity of ores with a high hafnium-zirconium ratio over that of the more abundant zirconium ores is due to the presence of uranium and thorium oxides.

METEOROLOGICAL DATA OVER THE OCEANS.—From various sources the Royal Netherlands Meteorological Institute has produced some useful tables of monthly meteorological data over the oceans for the year 1921 (Bulletins 6^1 and 6^2). The computations are for ten-degree squares and give the mean force and direction of the wind, the atmospheric pressure, air and water temperature, and cloudiness. In the Atlantic Ocean the data are given between 5° to 25° N. and 25° to 45° W. and between 0° to 20° S. and 10° E. to 10° W. ; in the Indian Ocean between 10° and 20° N. from 70° to 90° E. and between 10° and 30° S. from 90° to 110° E. ; while in the Pacific Ocean the limits are 10° to 30° N. and 140° to 160° W., and 10° to 20° S. and 90° to 110° W. The observations thus leave out of account large areas of the oceans especially in high latitudes, and are not complete in many parts of the Pacific Ocean within the limits given. But they can of course be obtained only on frequented trade routes. The number of observations in each month varies in different squares from one to more than a hundred. The corresponding data for 1917–1920 consisting only of Dutch observations are promised shortly.

FREE-AIR TEMPERATURES AND WIND DIRECTIONS.—The *Monthly Weather Review* for January, published by the U.S. Weather Bureau, has an article by Mr. W. R. Gregg showing the relations between the above.

The purpose of the discussion is to utilise, for the advancement of the subject, the available free-air observations made in the United States from 1915 to the present time. All observations made with kites are considered, but the discussion is chiefly confined to data from Drexel, Nebr., and Ellendale, N. Dak. Observations of wind and temperature are grouped for 16 points of the compass for the surface, and for one, two, three, and four thousand metres above sea-level for each station, also for spring, summer, autumn, winter, and the year. The observations with N.N.W. to N.N.E. and S.S.E. to S.S.W., with distinctly north and south components, are separately combined for each elevation. At all levels to at least 4 kilometres much higher temperatures prevail with south component than with north component surface winds. Differences are smallest in summer, averaging about 5° C. The differences are greatest at 1 and 2 kilometres, but at 4 kilometres they average 7° to 8° C. It is pointed out that the free-air position of a low barometrical centre is usually to the north-west of the sea-level position, and that of a high to the south-west, so that winds are south-westerly above the sea-level positions of lows and north-westerly above the sea-level positions of highs, and consequently the air above lows is warmer than that above highs. Taking the lowest and highest pressures at different heights as the basis of comparison, it is found that the lowest pressures are accompanied by the lowest temperatures, the pressure itself at any level being largely a function of the mean temperature of the air column beneath. Numerous examples and charts are given, showing the influence of the source of air supply on the changes of temperature experienced during the passage of areas of low and high barometer. The discussion is of great value to experimental meteorology.

ADSORPTION.—Since Gibbs deduced an equation for the change of concentration of a dissolved substance at the surface of separation of its solution from another material, in terms of the rate of change of surface energy with concentration, attempts have been made to test its validity by experiment. The most successful experiments up to the present were those of Donnan and Barker in 1911. J. H. Mathews and A. J. Stamm, in the May number of the Journal of the American Chemical Society, describe experiments at a liquid-liquid interface, using a drop-weight method. Solutions of dimethylaniline in heptane and in benzene were used. The qualitative results confirmed Gibbs' formula, and by calculation from the quantitative results Langmuir's theory of adsorption was found to be verified, namely, the adsorption is one molecule thick up to concentrations where a complete surface layer is formed. The molecular thicknesses and cross-sections agree with those of other investigators.

APPARENT SELECTIVE REFLECTION OF X-RAYS BY CRYSTALS.—Dr. W. Kossel, in the *Zeitschrift für Physik* for May, deals with the observations of Clark and Duane, which these authors have interpreted as indicating selective reflection. Kossel points out that, according to the ideas of the mechanism of radiation held up to the present, a coherence between the radiation of separate atoms, such as is required to explain selective reflection, is not to be expected, since the times during which they are excited are supposed to be irregularly distributed. He finds it possible to explain a good deal of the experimental material of Clark and Duane, in part quantitatively, by considering the variations of the absorption coefficient of the crystal. X-rays of wave lengths for which the coefficient of absorption is small penetrate to a greater depth into the crystal than those for which it is large, and stronger interference effects are produced by the crystal lattice with the first than with the second. It seems doubtful whether any new phenomenon, which can be described as selective reflection, is involved.

MAGNETON NUMBERS AND ATOMIC STRUCTURE.—It is interesting to note that a certain amount of scientific work is still being carried out in Russia. Dr. J. Dorfmann contributes a paper, dated from Leningrad, to the May issue of the *Zeitschrift für Physik*, in which he puts forward a series of hypotheses as to the relation between the electron orbits of the elements, and their magnetic properties. Bohr has shown that atoms with a closed electronic configuration, where the orbit groups contain 2, 4, 6, 8 similar n_k orbits, are diamagnetic; and that paramagnetism appears when they contain 1, 3, 5, 7 orbits. If there is only one electron in an orbit group, the magnetic moment due to it is given in Bohr units, by the k number of the orbit; the author assumes that, with a group having 3, 5, 7 or $2p+1$ orbits, $2p$ of them form a symmetrical diamagnetic complex, while one of them takes part in the paramagnetism, and contributes a moment of k units to the atom. The moments due to different asymmetrical orbit groups are supposed to add, when the principal quantum number n is the same for all the groups concerned; while for different values of n they are regarded as combining vectorially. Orbit configurations have been worked out for different ions of the elements between scandium and zinc; and values of the magnetic moments have been calculated, on the above assumptions, which agree quite well with the observed values. A similar table is given for the elements from lanthanum to hafnium, for which, however, the observational data are not quite complete.

STEAM-NOZZLES.—The third report of the Steam-Nozzles Research Committee has now been presented to the Institution of Mechanical Engineers, and comprises (*a*) tests on convergent impulse nozzles, 20° nominal angle, with thick partition plates; (*b*) a series of tests to determine the effect of chamfer on the exit edges of comparatively thick plates; (*c*) work on the $\frac{3}{8}$-inch Parsons standard 430 B blades, which emphasises the effect of entry on nozzle efficiency; (*d*) the first test results of a set of straight elementary nozzles designed by Prof. A. L. Mellanby. The general shape of the curves obtained for the velocity coefficients of steam-nozzles (given in the second report) has been corroborated, and in one or two cases the curve has been carried sufficiently far into the low velocity region to indicate that it "turns over" as predicted by Mr. Martin. The effect of chamfering thick plates of convergent nozzles is clearly shown in the present report; it would appear that a thick plate nozzle with a chamfered exit can be made as efficient, over a considerable working range, as a nozzle with very thin plates. A straight elementary nozzle is in general 5 per cent. more efficient than the practical types of nozzles which have been tested. A review of both second and third reports goes to show that the condition of entry or of exit is important; the steam should approach the nozzle as smoothly and as slowly as possible, and no flat surfaces should be left on the exit side of any nozzle. There are other interesting conclusions on the effect of superheat, for which reference should be made to the report. The work of the committee is proceeding without interruption, and has been greatly assisted by contributions from the British Electrical and Allied Industries Research Association.

International Conference on Soil Science.

THE fourth International Conference on Soil Science was held in the building of the International Institute of Agriculture at Rome on May 12-19, when between 120 and 150 delegates from various countries were present. The Ministry of Agriculture appointed the following delegates from Great Britain : Dr. N. M. Comber, Dr. B. A. Keen, Mr. H. J. Page, and Mr. G. W. Robinson.

The general organisation of the conference was in the hands of Prof. Hissink, of Groningen, Holland, and the actual arrangements for the meeting were carried out by local committees in Rome.

In all, some 250 papers were presented to the conference, distributed over the following sections :

1. (*a*) Physical Properties, and Mechanical Analysis of Soil.
   (*b*) Application of Soil Science to Field Conditions.
2. Chemical Properties of Soil.
3. Biochemical and Bacteriological Studies.
4. Soil Classification.
5. Soil Surveys and Maps.
6. Physiological Studies in Relation to Soil.

These sections met both independently for the consideration of their own papers, and jointly for discussions of common interest.

In addition, the following lectures were given during the conference :

La nitrification et ses conséquences agricoles, Prof. G. André (Paris) ; Recent Advances in Soil Physics, Dr. B. A. Keen (Rothamsted) ; Dispersoidchemie und Bodenkunde, Prof. G. Wiegner (Zurich) ; Die modernen Ziele zur Erforschung der Bakterientätigkeit im Boden, Prof. J. Stoklasa (Prague) ; The Fertiliser Industry of the United States in Relation to Soil Science, Prof. J. G. Lipman (New Jersey) ; Analisi del terreno e suo valore, Prof. A. Menozzi (Milan).

Some considerable time before the conference, arrangements had been made for certain outstanding questions to be studied co-operatively by workers in different countries. The reports of these investigations formed an important section of the conference. Among them may be mentioned an investigation of the various methods employed for dispersing soil samples prior to a mechanical analysis. Samples of two given soils were distributed to each worker so that the results of the various methods were strictly comparable. The mechanical analyses showed considerable variations, not only among the different methods, but also for the same method in the hands of different workers. The studies are to be continued and extended in view of the vital importance of complete dispersion of the soil suspension for the newer methods of mechanical analysis, such as those of Odén and Robinson, which depend on one single sedimentation.

Further joint discussions took place on the question of base exchange in soils and on the production and cause of soil acidity. It cannot be said that any general agreement emerged from these discussions, nor in the present state of our knowledge would this be expected. The contributions of Ramann and Wiegner on base exchange were noteworthy. The former supported the view that base exchange alone is produced by neutral salts ; hydroxides and salts with alkaline reaction give base exchange and adsorption ; acids and acid salts decompose the silicates, and an exchange between the cations of the silicates and the hydrogen of the acids causes the formation of acid soils. Wiegner developed the view that base exchange in clay or soil is a special case of the so-called "polar" exchange-adsorption, and is intimately linked up with the degree of dispersion of the clay. On this view a clay particle may consist of an aggregate of smaller particles. The total surface of the compound particle is available for base exchange phenomena, while the electrical properties of the aggregate are a function of its outer surface only.

All the six sections combined for the discussion on soil acidity. The chief value of this discussion, which extended over too wide a range for an adequate summary to be given here, was the opportunity afforded for those studying the subject from the physico-chemical aspect to appreciate the problem from the physiological point of view, and vice versa. A number of the speakers dealt with the efforts made to develop a field technique on which practical recommendations as to liming could be based. Prof. Hissink described his quantitative adaptation of the well-known Comber test for sour soils that was now in extensive use in Holland as a means of measuring lime requirement. Dr. Comber directed attention to the danger in assuming that any qualitative test that showed a reasonable degree of quantitative relationship for any given soil type was suitable for general application.

Special mention must be made of the work of Section 5. In the face of considerable difficulties, financial and otherwise, a very complete account of the present position of soil survey work was collected from experts in many different countries. With the assistance of the Geological Institute of Rumania, Bucharest, Profs. Murgoci and Opresco were able to have these memoirs printed for distribution to the conference. The volume forms a most valuable record of the present state of the subject, and will be of great value for comparative studies.

In connexion with the conference, a small exhibition of apparatus, maps, etc., was held. Several members took this opportunity of demonstrating the apparatus they had already described at the conference. The younger German workers are showing considerable activity in devising field instruments. The problem of measuring the moisture content of soils *in situ* by means of the electrical resistance has been attempted before, but the apparatus was not satisfactory. The new method of Dr. Götz, of Berlin, is based on the same principle, but is a distinct improvement and appears to be of great promise. Dr. Trenel, of Berlin, demonstrated an apparatus for measuring the P_H of soils *in situ*.

Perhaps the chief value of a conference such as this lies not so much in the meetings and reports as in the numerous opportunities afforded for informal discussions with workers from other countries. The conference was well served in this respect, as the local committee arranged several receptions and excursions during the meeting. The Italian Government took an active interest in the proceedings ; the King was present at the opening of the conference, and the Minister of National Economy attended the closing meeting.

The final act of the conference was to establish an International Society of Soil Science, having as objects the promotion of soil science by means of conferences, the formation of special committees for co-operative work, the publication of a review, and the institution of a central office in the International Institute of Agriculture at Rome, where all reports and documents can be filed, and from which members can obtain information needed in their work.

The first president is Prof. J. G. Lipman, of the New Jersey Experimental Station, and on his invitation, the conference appointed America as the place for the fifth meeting. The following were elected

honorary members: Prof. Cayeux (France), Prof. Glinka (Russia), Prof. Murgoci (Rumania), Prof. Ramann (Germany), Sir John Russell (England), and Prof. Winogradsky (France). The acting-chairman and general secretary is Prof. Hissink, Groningen, Holland. The International Mitteilungen für Bodenkunde has been taken over as the official journal of the society, and will be in future published by the International Institute of Agriculture at Rome.

The society has undoubtedly an important future, and it is hoped that it will have many British members. Further information can be obtained from either Prof. Hissink or Dr. B. A. Keen, Rothamsted Experimental Station, Harpenden. B. A. KEEN.

International Mathematical Congress.

DURING next August, Toronto is to be the scene of two great scientific gatherings. The British Association will hold its ninety-second annual meeting on August 6-13, and an International Mathematical Congress will be held on August 11-16. International gatherings of mathematicians have previously been held in Zurich (1897), Paris (1900), Heidelberg (1904), Rome (1908), Cambridge (1912), and in Strasbourg (1920). The North American continent is for the first time the meeting place of such an assembly. The natural boundary of distance, with the incident expense of transportation, is being in a large measure overcome by the generosity of the Governments of the Dominion of Canada and the Province of Ontario, each of which is making a contribution of 25,000 dollars to defray the expenses of the Congress. The greater part of these funds will be used to assist the passage of eminent European men of science, mathematicians, and representatives of those sciences and professions which apply mathematics. It is estimated that the attendance from Europe will exceed one hundred and fifty. The British representation on the applied side promises to be large. At least twenty will come from France, nearly as many from the Scandinavian countries, and more than a dozen from Italy. Not less than fifteen European countries will be represented. The attendance from Canada and the United States is expected to run into the hundreds.

Difficulties in arranging suitable dates for the Congress delayed the sending out of notifications. The Organising Committee has tried to notify all those likely to be interested resident in countries adherent to the International Mathematical Union, or eligible for adherence thereto. In all, some six thousand notifications have been sent out, and a large number of universities and learned societies have been invited to be represented by delegates. Among those bodies which will be represented are the National Committees of the International Mathematical Union. These Committees are, as a rule, appointed by the National Academies of the respective countries, and through them the Academies might be regarded as obtaining representation. Many of the Academies, however, will, in addition, be directly represented. This, for example, will be the case with the Reale Accademia dei Lincei and the Académie des Sciences de l'Institut de France. Many specialised scientific societies too have named delegates. Among such are the Société Mathématique de France, the Circolo Matematico di Palermo, the American Mathematical Society, the Physical Society of London, the Société Française de Physique, the Royal Astronomical Society, the Royal Meteorological Society, and sister societies in a number of different countries. Statistical and actuarial societies will also be represented. The Institution of Naval Architects, the Institution of Electrical Engineers, the Institution of Mechanical Engineers, and other engineering organisations have appointed representatives. The same is true of the British Association and the corresponding organisations in France and the United States. The National Physical Laboratory and the Bureau of Standards have also named delegates, while many universities will be represented, including, among others, Cambridge, Paris, and Rome.

The Congress is being held under the auspices of the University of Toronto and the Royal Canadian Institute, and will be conducted in accordance with the regulations of the International Research Council. Prof. J. C. Fields, president of the Royal Canadian Institute, is chairman of the Organising Committee, and the other members of the Committee are Sir Robert Falconer, president of the University of Toronto, Prof. A. T. DeLury, Prof. J. C. McLennan, Prof. C. A. Chant, Mr. T. H. Hogg, Dr. J. S. Plaskett, Prof. M. A. Mackenzie, Prof. E. F. Burton, Mr. J. Patterson, Mr. W. P. Dobson, Wing-Commander E. W. Stedman, and Prof. J. L. Synge (secretary). Dr. F. A. Mouré, bursar of the University of Toronto, is acting as treasurer. An Editorial Committee has been organised, with Prof. Fields as chairman. There are also associate committees to deal with hospitality, excursions, printing, publicity, meeting rooms, signs and messengers, finance and transportation.

An excursion has been arranged for a selected party to the Western Provinces on special trains, leaving Toronto on the night of Sunday, August 17, and returning in about three weeks' time. There will also be an excursion through Northern Ontario, and excursions to Niagara Falls on August 9 and August 16, the route being by steamer across Lake Ontario, the journey each way taking about two hours.

The Congress will meet in the following sections:

Section I. Algebra, theory of numbers, analysis.
Section II. Geometry.
Section III. (*a*) Mechanics, mathematical physics.
(*b*) Astronomy, geophysics.
Section IV. (*a*) Electrical, mechanical, civil and mining engineering.
(*b*) Aeronautics, naval architecture, ballistics, radiotelegraphy.
Section V. Statistics, actuarial science, economics.
Section VI. History, philosophy, didactics.

It will be observed that this scheme of sections differs from those adopted at former congresses in the additional attention devoted to the applications of mathematics. It has been devised in order to secure in the sphere of applied mathematics full opportunity for consideration not only of those questions the interest of which is purely scientific, but also practical problems of engineering the solutions of which contribute directly to the cause of material progress.

The Organising Committee would be obliged if those who expect to attend the Congress would notify the secretary to that effect, stating their order of preference in accommodation from a choice of hotel, boarding-house, or university residence. Abstracts of papers intended for presentation should be in the hands of the secretary well in advance of the meeting.

Further information may be obtained from Prof. J. L. Synge, secretary of the Organising Committee, International Mathematical Congress, Royal Canadian Institute, 198 College Street, Toronto, Canada.

The Physical and Physico-chemical Problems relating to Textile Fibres.

IN the joint discussion held by the Faraday Society and the Textile Institute at the British Empire Exhibition, Wembley, on June 11, under the presidency of Sir Robert Robertson and Mr. Lester, a number of important developments of research on textile fibres was disclosed. The papers covered a wide field and dealt with the physical properties of cotton, wool, flax, and silk fibres. It is intended in this article to describe some of the points raised during the discussion rather than to refer in detail to the subject-matter of the papers, which is to be published later.

The introductory address was given by Dr. W. L. Balls, who proposed to divide physical research in textiles into two sections: (1) that relating to the physical unit in each raw material; and (2) that relating to the larger field concerned with the building up of the yarn and fabric. The appropriateness of this division is at once apparent; it separates, at least vaguely, the bio-physical problems from the mechanical ones, implying by the latter those problems concerned in the transformation of a mass of raw material into a useful yarn or fabric. In his conclusion Dr. Balls said: "The defects of yarn and fabrics which admittedly exist, together with other defects whose existence is not even recognised, were formerly due to faults in the machinery employed. Many of these have been eliminated in the course of time; and the physicist is now concerned rather with studying the causation of defects which are inherent in the properties of the raw material."

This warrants a note of criticism. The present writer pointed out that though the importance of physical tests on raw materials cannot perhaps be overstated, at any rate from the grower's point of view, yet at the same time it should be clearly understood that there are, on the industrial side, limitations to the profitableness of such work. I refer particularly to trade samples of raw material. It would no doubt be an easy though laborious matter to obtain valuable information concerning certain characteristics of the cotton fibres and their correlations, for example, provided one confines the effort to one or more special varieties. But it must be borne in mind that the practical spinner has no direct interest in special varieties; he buys and mixes his raw material according to market prices. Such raw material makes physical research on the "textile unit" a most uncertain and despondent field when the results are interpreted according to the expectations of the spinner or manufacturer. To take an example, it is now known that the lustre of a doubled yarn depends on a certain relationship between the constants for spinning the singles and for doubling them. If this condition is not satisfied, it is easy to make a highly lustrous raw cotton into a less lustrous yarn than might have been produced by using a less lustrous cotton and working it properly. This is quite apart from the measurable characteristics of raw cottons, such as staple length, fineness, or convolutions, etc., and shows that the relative *position* of the fibres, determined by the spinning processes, is at least as important as the properties of isolated fibres. Again, the percentage irregularities of yarns spun from high- and low-grade cottons are about the same, so that this important property does not depend appreciably on the raw material. Such examples might be multiplied a hundred-fold. While not denying that many of the defects existent in yarns and fabrics are rightly concerned with variability in the raw material, it is necessary to emphasise the fact that many defects are traceable to the machines, scarcely one of which, in the writer's opinion, cannot be improved by physical research. Dr. Balls' remark that "the utility of the scientist in industry is largely conditioned by the degree of stability of the industry" is only too true; it enforces the necessity for work on the complex mixtures of raw material almost universally used in practice, and leads us to the conclusion that work of this character is the more immediate. Furthermore, it is the duty of the Textile Industrial Research Associations to supply such practical information while still keeping a preserve for work on "textile units," which, it is hoped, will eventually be of vital importance to the producer of the raw material.

Dr. S. A. Shorter dealt with the nature of the recovery from strain of the wool fibre, in particular, attributing the creep to the combined effects of elastic and impeded elastic portions of the fibre structure rather than to its plasticity, to which property other authors have ascribed the effects. He stated that the elasticity of wool approaches the ideal, the hysteresis being almost entirely a true effect, and suggested that the fibre acts as a two-phase system, including (*a*) a perfectly elastic framework, (*b*) a viscous fluid; the two affording a complete explanation of the phenomena observed in the finishing of woollen and worsted fabrics. Mechanical models were described to illustrate the type of structure advocated, and the system of impeded elastic elements was used to explain how the shedding fault arises in a loom which has been standing over (say) the week-end.

Some experiments on loaded gelatin sticks were described by Mr. Pool, who concluded that the elastic effects observed in such purely colloidal systems were analogous to those simulated by Shorter's model. It was pointed out by Dr. Mardles that similar effects were common in many materials, *e.g.* steels, time and stress introducing new phases initiated by molecular changes. Mr. Peirce thought the effects were due to impeded but reversible orientations within the mass and these effects were ultimately inherent in the molecules themselves. In his paper on the fibre balance, Dr. Barratt described load-extension diagrams showing the relative degree of non-recovery from strain in wool, cotton, silk (viscose) and flax, the order, as indicated, being decreasing. Dr. Shorter was of the opinion that in the case of the wool fibre, practically all the residual strain would disappear by wetting, while he agreed that with cotton fibres a small amount of non-recovery persists.

Two important communications were made by Dr. T. Barratt on the lustre of cotton fibres and the transparency of fabrics. The lustre comparisons were made by a special arrangement of a Joly photometer, the fibre pads being so mounted that varying angles of incidence and diffusion could be obtained, and also so that they could be rotated in their own plane. Unmercerised and mercerised cotton and glass fibres were tested and the conclusions drawn that (1) the light reflected from a mercerised fibre in certain positions is concentrated within a small angle; (2) the light from an unmercerised (twisted) fibre is scattered over a wide angle; and (3) the lustre is enhanced when a number of mercerised fibres are laid parallel to each other (the case of a sateen with "floating" threads). The increased lustre shown by a mercerised fibre is due to light regularly reflected in a plane containing the length of the fibre. In keeping with this result, the work of the writer and Mr. Adderley was mentioned, which showed that in doubled yarns the optimum lustre was obtained when the fibres in the doubled yarn are parallel to its axis, so that, looking

along the yarn, the light is mainly reflected along the length of the fibres.

Using the Joly photometer, measurements of (1) the total transparency of fabrics (defined as percentage of incident light transmitted), (2) thread transparency (the percentage of light falling on the threads alone, which is transmitted), were made. The determination (2) was made possible by dyeing the threads black and so obtaining a measure of the light transmitted by the spaces alone. From the combined readings it is then possible to calculate the total light incident on threads *alone* and that transmitted by threads *alone*, which is a measure of thread transparency.

Mr. C. R. Nodder showed slides of the structural characteristics of compressed flax fibres, up to fifty daily growth rings being visible, and also the spiral fibrillæ in each layer. Herzog and Jancke have obtained X-ray point diagrams with flax and ramie fibres which they attribute to a rhombic (or monoclinic) symmetry of constituent crystallites. With powdered fibres they obtained diffraction rings confirming this result. Flax and ramie fibres subjected to similar compression presented optical effects which indicate the true crystalline nature of their structure.

A large number of physical data relating to the silk fibre (the ultimate filament of fibroin, two of which, gummed together by sericin, form the cocoon thread) were detailed by Dr. W. S. Denham. The most interesting of these concern the crystalline structure found by Herzog and Jancke. Some measurements on the lustre of silk fibres with the plane of incidence perpendicular and parallel to the fibre length were discussed in terms of the arbitrary expressions for lustre recommended by Zart, Schultz, and Adderley, and Dr. Denham reasonably advocated some universal standard. The lustre is greater with the plane of incidence containing the fibre length (cf. Barratt, *supra*). The thermal conductivities of textiles have been measured by Miss Rood; the values, for the same density, increasing in the order, silk, wool, artificial silk, linen, and cotton.

An interesting account of experiments on the tautness of aero-fabrics was given by Dr. Ramsbottom, who pointed out that though dope may be regarded as the primary factor in fixing tautness, still the nature of the fabric is of importance in maintaining this property at high humidities and after long exposure. Fabrics woven from fine yarns preserve tautness better than those containing coarser yarns, and linen, cotton, and silk all give satisfactory tautness at low humidities. With cotton and linen, at high humidities the tautness falls but recovers with absorption of water by the fabric, whereas with silk the tautness falls off continuously, so that silk fabrics are inferior to others. Mercerised cotton is preferable to unmercerised cotton or linen. Measurements on strength and deterioration on weathering were given. Dr. de Waele asked if it were possible to obtain a mesh of (say) silk and cotton which would have constant tautness, in reply to which Mr. Crompton said it was quite feasible to double artificial silk and cotton to test this point.

The action of light on textiles was discussed by Dr. Barr, who laid stress on the difficulties of measuring the photochemical action due to sunlight, which is the real aim of such research. With sunlight the spectrographic method has given negative results, while only incomplete data have been obtained by using glass screens. The method of first dyeing the fibres and exposing them to white light has given some practical results, but these are difficult to interpret, being complicated by the ill-defined nature of the light stimulating the reaction and the possibility of unknown interaction between fibre, dye, and the reaction products.

With the mercury arc in quartz, rapid deterioration of textile fibres may be developed, but such effects cannot be safely translated into terms of sunlight. Cellulose is very sensitive to wave-lengths less than 3000 Å.U., which exist in the mercury arc but not in sunlight. Aston's work on cotton and linen threads (for aero-fabrics) indicates that with light from the mercury arc, the most destructive rays have wave-lengths less than 3990 Å.U., a conclusion which has been verified by Ramsbottom by using coloured glass screens. Two hundred hours' exposure to sunlight produced no effect. Assuming that ionised oxygen is responsible for the deterioration, Lindemann has deduced from the quantum theory that the most destructive radiation has a wave-length of 3230 Å.U.

Very little is known about the tendering action of light on other textile fibres. Silk appears to be considerably more affected than linen, while wool is almost immune.

Mr. F. D. Farrow referred to some recent advances in the experimental study of warp sizing, and dealt with the work of Owen and New on the oscillating resisting properties of yarns, and that of Farrow and Lowe on the viscosity of starch pastes. The work on viscosity involves a modified Poiseuille's equation, a "coefficient of flow" being measured which is proportional to a power of the pressure, the index varying between 1 and 2.

A review of the recent work on the moisture relations of textile materials was contributed by Mr. A. R. Urquhart and Dr. A. M. Williams. The hysteresis effects observed in the authors' work have been interpreted in terms of Zsigmondy's theory of the existence of capillary spaces within a gel, which, in the case of cotton, have a diameter of the order 13×10^{-8} cm. A study of the rates of absorption and desorption indicates that these processes are discontinuous.

A paper on the effect of water in the wet-spinning of flax was given by Dr. W. H. Gibson, who held the view that the process was conditioned by a gradual variation in the fibre constitution from pectin through intermediate products to cellulose. There is apparently a considerable breakage of the fibres (about 12 in. long) with a drafting reach of $3\frac{1}{4}$ in., as might be expected, and frequency curves showing the displacement of the breaking load modes of the yarn and rove confirm this.

In addition to the papers submitted for discussion, a number of interesting slides of linen fabrics from Tutankhamen's tomb were exhibited by Dr. A. Scott. These depicted (*a*) a linen veil, unbleached, 150-160 threads per inch × 80 threads per inch, in reflected and transmitted light; (*b*) a pall of much coarser linen fabric; and (*c*) a very friable linen fabric having two threads one way and one the other.

Sir Robert Robertson pointed out the great importance of obtaining further knowledge of the action of light on fabrics, and Mr. Lester remarked that we knew next to nothing about the life of a fabric, recalling the process of laundering and the effect of acid. In a few months a fabric might lose 60 per cent. of its strength.

A. E. OXLEY.

University and Educational Intelligence.

BIRMINGHAM.—The degree of Ph.D. has been awarded to the following candidates, the subjects of the theses being indicated in each case: Mr. N. F. Budgen (Researches with cadmium); Mr. Denis Bunting (An investigation of the brittle ranges of brass); Mr. Kamil Iskander (The development of precision measuring instruments for the determination of the heating value of gases); Mr. T. D. Jones

(The strata temperatures of the South Wales coal field, and causes of variation in the same; Hygrometric observations in South Wales collieries).

DUBLIN.—Among the honorary degrees which have been conferred at Trinity College are the following: *D.Sc.*: Prof. R. A. Millikan, of the California Institute of Technology, Pasadena, and Prof. E. B. Poulton, Hope professor of zoology in the University of Oxford; *D.Litt.*: Prof. Ernest A. Gardner, Yates professor of archæology, University College, London.

LEEDS.—Mr. A. Seymour-Jones has presented to the Leather Industries Department his library, consisting of about 200 books on leather and kindred subjects, and a set of framed photomicrographs for display in the Department.

It has been decided to institute a lectureship in medical radiology and electro-therapeutics, and to appoint thereto Dr. Scargill and Dr. Cooper as joint lecturers. Mr. William Davies has been appointed demonstrator in engineering.

LONDON.—Prof. E. A. Gardner, Yates professor of archæology in the University, tenable at University College, has been elected Vice-Chancellor for 1924–25 in succession to Mr. H. J. Waring.

Dr. B. B. Baker has been appointed as from October 1 to the University chair of mathematics, tenable at the Royal Holloway College. Since 1920 Dr. Baker has been lecturer in mathematics at the University of Edinburgh; in 1921 he was elected a fellow of the Royal Society of Edinburgh and hon. secretary of the Edinburgh Mathematical Society. His published work includes various articles in mathematical and scientific journals.

Dr. C. L. Burt has been appointed as from August 1 to the University (part-time) chair of education, tenable at the London Day Training College. From 1908 to 1912 Dr. Burt was lecturer in experimental psychology in the University of Liverpool, and from 1912 to 1913 assistant lecturer in the Psychological Laboratory, Cambridge. Since 1913 he has been psychologist in the Education Department of the London County Council. He has published a number of works on intelligence tests and allied subjects.

The title of professor of surgery in the University has been conferred on Dr. C. C. Choyce in respect of his appointment as Director of the Surgical Unit at University College Hospital Medical School.

The title of reader in geology in the University has been conferred on Mr. H. Gladstone Smith in respect of the post held by him at East London College. Mr. Smith has been lecturer in geology at East London College since 1918.

The title of professor of physics in the University has been conferred on Prof. O. W. Richardson in respect of his part-time appointment as Director of Research in the Department of Physics at King's College. Prof. Richardson will cease to hold the Wheatstone chair of physics, which he has occupied since 1914, on taking up the Yarrow Research Professorship of the Royal Society on August 1.

Sir Hermann Gollancz has given his library to University College to commemorate his twenty-one years' tenure of the Goldsmid professorship of Hebrew. Mrs. Preedy has presented to the University library a valuable collection of books on Greek and Roman archæology and art, formerly belonging to her son, the late J. B. Knowlton Preedy, who served for some years prior to the War as a secretary in the University Extension Department.

The following doctorates have been conferred:—D.Sc. (*Chemistry*): Miss M. L. V. Gayler (Bedford College), for thesis entitled "The Constitution and Age-hardening of the Quaternary Alloys of Aluminium, Copper, Magnesium, and Magnesium Silicide"; D.Sc. (*Physiology*): Mr. J. A. Hewitt (King's College), for a thesis entitled "Metabolism of Carbohydrates (Part III.)"; D.Sc. (*Physiology*): Mr. F. M. R. Walshe (University College and University College Hospital Medical School), for a thesis entitled "(i.) The Physiological Significance of the Reflex Phenomena in Spastic Paralysis of the Lower Limbs, (ii.) On certain Tonic or Postural Reflexes in Man, with special reference to the so-called 'Associated Movements,' (iii.) On Variations in the form of Reflex Movements, notably the Babinski plantar response, under different degrees of Spasticity and under the influence of Magnus and de Kleijn's Tonic Neck Reflex"; D.Sc. (*Geology*): Mr. Ernest Neaverson, for a thesis entitled "Ammonites from the Upper Kimmeridge Clay."

A degree of M.Sc. in the principles, history, and method of science has been instituted for both internal and external students.

MANCHESTER.—Applications are invited for the headship of the department of pure and applied physics in the College of Technology. The position carries with it the title and status of lecturer in the University. The latest date for the receipt of applications, which should be sent to the Registrar of the College, is July 16.

OXFORD.—Among the recipients of honorary degrees at the Encænia held on June 25 were Sir Humphry Rolleston, Bart., president of the Royal College of Physicians, and Prof. S. Alexander, professor of philosophy in the University of Manchester, who received the degrees of D.Sc. and D.Litt. respectively.

PROF. SYDNEY CHAPMAN, at present professor of mathematics and natural philosophy in the University of Manchester, has accepted the invitation of the Governing Body of the Imperial College of Science and Technology to undertake the chief professorship of mathematics at the Imperial College beginning in September next, in succession to Prof. A. N. Whitehead, who has been appointed to the chair of philosophy at Harvard University, U.S.A.

AT the universities' conference held at Simla in May it was decided that an Indian inter-university board should be constituted with one representative of each university, to facilitate the co-ordination of university work, to assist in obtaining recognition in other countries of Indian degrees, diplomas, and examinations, to act as an appointments bureau for Indian universities, to facilitate the exchange of professors, and generally to fulfil such duties as may be assigned to it from time to time by the Indian universities. The cost of maintenance of the board is to be met by equal contributions from the universities, but the Government of India and the provincial governments are to be asked to make a grant towards its expense. It has for some years been recognised that some such co-ordinating body was needed, and in April 1920 a committee was formed for drafting an outline of its functions and constitution. The project was further advanced at the Congress of Universities of the Empire in 1921, but the universities were not unanimously in favour of the proposals then formulated. The board now to be set up will be the Indian counterpart of the Conference of Canadian Universities, the Standing Advisory Committee of the Australian Universities, the Vice-Chancellors' Committee of South Africa, and the Standing Committee of Vice-Chancellors and Principals of the Universities of Great Britain and Ireland.

Early Science at the Royal Society.

June 29, 1681. In discussion the president [Wren] observed, that it was necessary, that all wholesome food should have oils: that most roots wanting oil are not of themselves a good nourishment: and that in Ireland, where the people feed much on potatoes, they help themselves by drinking milk soured, to make the potatoes digest the better.

June 30, 1686. Ordered, that the treasurer, to encourage the measuring of a degree of the earth, do give to Mr. Halley fifty pounds or fifty copies of the "History of Fishes," when he shall have measured a degree to the satisfaction of Sir Christopher Wren, the president, and Sir John Hoskyns.

July 1, 1663. Mons. Moncony's description of the way used in Egypt of hatching in ovens, was read, and ordered to be registered. He was of opinion, that the temperament of the air in Egypt contributed greatly to the method of hatching chickens, since the grand duke having sent for some of the christians of Cairo, who are the only persons, that carry on that business, they had built an oven at Florence, but failed of hatching chickens.

1680. Sir Christopher Wren affirmed, that extreme freezing will sweeten salt water: that the curd which is then upon the surface of the water, will be found sweet: that this is found in Hudson's Bay: and that a little hole left in a window in winter, and a little fire in the chimney, will freeze anything to a great degree.

July 2, 1662. It was ordered that the committee appointed to view the Towgood's engine, meet the Saturday following afternoon in the Temple church. —A new astronomical hypothesis of a stranger was referred to the consideration of Dr. Wren [and others].

1668. The experiments appointed for this meeting not being prepared by reason of the operator's indisposition, it was ordered that on the like occasion another person should be hired and made use of *pro tempore* to do the manual part, that the Society might not be destitute of experiments.

July 3, 1661. Mr. Croune to procure, against the next meeting, some fresh vipers; and the operator to provide fresh hazel-sticks.—Mr. Evelyn presented his relation of graving and etching; and, after public thanks returned to him, was requested to transcribe it.

1672. Dr. Grew was put in mind to see, what might be discovered of the peristaltic motion in plants, asserted by Signor Malpighi.—Mr. Hooke was called upon for making a report concerning Signor Cassini's paper concerning the satellites of Jupiter, and desired to give in writing what he had said upon it that it might be without mistake imparted to Signor Cassini, who had desired that favour.

1679. It was ordered that Mons. Papin be employed for the writing of all such letters, as shall be ordered, to the correspondents of the Society: and that for so doing the said Mons. Papin shall receive the sum of eighteen pence per letter, unless the letter shall exceed two sides of a quarter of a sheet of paper; for every of which he shall receive two shillings.

July 4, 1678. A letter was read to the meeting written by Jacobus Pighius, dated at Padua, wherein he expressed the high respect which he had for the Society, and his great desire of being known to them. He mentioned his esteem for the English in general, and the favour done him by the English students at Padua, in choosing him their pro-syndic.

1683. It being thought proper, that some man should be appointed to keep the door of the meeting-room during the time that the Society was assembled, the porter, who removed the seats, was ordered to wait, and to have 12*d.* a time, when he waited.

Societies and Academies.

LONDON.

Royal Society, June 19.—J. C. **McLennan** and G. M. **Shrum**: On the luminescence of nitrogen, argon and other condensed gases at very low temperatures. Experiments are described on the luminescence of nitrogen and argon at the temperature of liquid hydrogen under electronic irradiation. The spectra of the light emitted by both elements contains wavelengths close to but not coincident with that corresponding to the auroral green line. Both solid nitrogen and solid argon phosphoresced brilliantly under electronic excitation. From these experiments there is no confirmation of Vegard's theory that the auroral green line originates in vaporous solidified nitrogen.—H. Grayson **Smith**: On the fine structure of the band spectra of sodium, potassium and sodium-potassium vapours. Four bands of the blue-green group of the band absorption spectrum of sodium and three bands of the red group of the band spectrum of potassium have been examined. Two values of the moment of inertia of the normal sodium molecule have been found from different bands, $2{\cdot}515$ and $2{\cdot}286 \times 10^{-39}$ gm.cm.^{2}. Assuming that the molecule is diatomic, the corresponding values for the distance between the nuclei are $1{\cdot}151$ and $1{\cdot}098 \times 10^{-8}$ cm. The moment of inertia of the potassium molecule is $18{\cdot}39 \times 10^{-39}$ gm.cm.^{2}, so that the distance between the nuclei of a diatomic molecule is $3{\cdot}069 \times 10^{-8}$ cm., which is in fair agreement with X-ray measurements. Two bands of a new group found by Barratt in the absorption spectrum of a mixture of sodium and potassium vapours give a moment of inertia of $6{\cdot}615 \times 10^{-39}$ gm.cm.^{2}. This agrees with the supposition that these bands are due to NaK molecules, the distance between the nuclei being $2{\cdot}137 \times 10^{-8}$ c.m.—Lord **Rayleigh**: (1) The non-luminous oxidation of phosphorus in an oxygen atmosphere. The views on phosphorescent combustion of phosphorus developed in former papers require that phosphorus vapour, when apparently inactive in an atmosphere of oxygen, should in reality be combining with it at isolated centres, though the action fails to spread. Either this action or the ordinary phosphorescent combustion can be caused to occur *at one given pressure and external temperature.* The rate of oxygen absorption is widely different in the two cases. With a given area of phosphorus surface, the rate of action is enormously increased by allowing a large oxygen space around it. The action occurs in the volume of the gas space, and therefore between oxygen and phosphorus vapour. (2) The light of the night sky: its intensity variations when analysed by colour filters. The comparison light is a uranium salt rendered self-luminous by radio-activity. Three alternative colour filters are provided; one of these approximately isolates the green aurora line. A red and a blue filter isolate the regions of the spectrum on either side of this line, excluding the line itself. The light of the sky as seen through these is equalised with the standard by means of neutral tinted glasses. Owing to faintness of the light, colour differences are not perceptible. Systematic observations of the auroral light for fifteen months, and of the other components for seven months, show variations which are far too large to be explained by changes in atmospheric transparency. The highest values of the auroral light were found during October 1923, which was the middle of a period of three months showing considerable sunspot activity. For the rest of the time there were few spots. The auroral light varies very little over the whole range of latitude from England to the Cape of Good

Hope. The polar aurora is contrasted with this non-polar aurora. The latter may be a phenomenon of phosphorescence, the luminosity being excited by the sun during daytime and carried round by the earth's rotation as in the phosphoroscope. The light of the night sky is much richer in red, measured relative to blue, than is daylight. In this respect it approximates to the light of a ½-watt incandescent lamp.—W. G. **Palmer** and F. H. **Constable**: The catalytic action of copper. Pt. IV. By measuring the velocity of dehydrogenation of alcohol passing over copper film catalysts when the temperature of the catalyst is rising and again when it is falling, a measure of the temperature coefficient of the change is obtained. Above a temperature of 280° C. the adsorbed alcohol film becomes unimolecular, and the aldehyde bombarding the bare copper surface polymerises and causes decay of the activity by covering the surface. No evidence of decay due to sintering was obtained during the experiments, which lasted up to five hours. The catalytic activity varied with the temperature of reduction of the copper oxide in a periodic manner; in general the greater the activity of the catalyst the less the temperature coefficient. Reduction at 420° C. seems to change both the grain structure and the nature of the surface. The "heat of activation" of an alcohol molecule is held to vary with the arrangement of the atoms in the surface on which it is adsorbed.—Rev. A. L. **Cortie**: The 27-day period (interval) in terrestrial magnetic disturbance. At a period approaching minimum solar activity (May 1921–July 1923), the persistence of notable magnetic disturbances in series at a 27-day interval, when the sun was entirely free from spots, and even sometimes of bright faculæ and flocculi, led to two long sequences of such disturbances, May 12, 1921–April 13, 1923, containing 26 synodic recurrences, and October 27, 1921–July 10, 1923, embracing 23 recurrences. In each sequence, from the magnetic data alone, a mean solar latitude has been computed, and a mean solar longitude, which fit accurately two regions of intermittent solar activity, one in the sun's northern hemisphere, and the other in the southern hemisphere. Moreover, these two regions, separated by about 180°, practically contained all the sunspots that had appeared in the period discussed. But there is no parity between the intensity of sunspot or floccular activity, and of magnetic disturbance. In the period discussed, magnetic disturbances occurred without, but not independently of, solar activity in a restricted area.—E. K. **Rideal** and C. G. L. **Wolf**: The destruction of rennin by agitation: a case of catalysis at an air-liquid interface. Rennin solutions undergo a chemical destruction when agitated, due to a chemical reaction occurring at the air liquid interface. The second reactant is a capillary active substance which is present in ordinary rennin solutions, but can be removed by dialysis. The dialysable reactive constituent is probably a fatty acid.—W. G. **Palmer**: The use of the coherer to investigate adsorption films. Loose contacts or "coherers" formed of tungsten-tungsten, carbon-tungsten, and platinum-platinum surfaces have been studied with particular regard to the action of the gas surrounding them. The voltage required across the contact to effect full metallic conduction is, for a given gas, a constant practically independent of the pressure of the gas and varying between wide limits for different gases. The cohering action may be due to the evaporation of an adsorbed film of gas under electrical stress. From the critical voltage the latent heat of evaporation of the film is calculated.—R. J. **Lang**: On the ultraviolet spark spectra of some of the elements. The wavelengths are given for the following elements: carbon, calcium, titanium, vanadium, chromium, manganese, cobalt, arsenic, molybdenum, cadmium, tin, antimony, tellurium, cerium, platinum, gold, thallium, lead, bismuth, uranium, in the ultraviolet region. They range from $\lambda = 2000$ A to $\lambda = 224$ A.—W. T. **Astbury** and Kathleen **Yardley**: Tabulated data for the examination of the 230 space-groups by homogeneous X-rays. Diagrams are given, one for each of the 230 space-groups, showing the distribution of symmetry elements and the relative positions and orientations of the molecules in the unit cell; and accompanying these diagrams are tables giving the fundamental Bravais lattice, the number of asymmetric molecules per cell, the abnormal spacings to be expected, and the possible molecular symmetry for each space-group.—J. W. **Campbell**: On the drift of spinning projectiles. The following assumptions are made: (1) The shell is stable. (2) Its initial rotation is all about the axis of symmetry. (3) The resistance of the air can be represented by two forces, one along the axis of symmetry of the shell, and the other at right angles to the axis and in the plane of the tangent to the trajectory and the axis, the latter force acting at some point (variable) in front of the centre of gravity of the shell. When the initial oscillations have been damped out by air resistance, (2) is practically realised. Experiments show that the principal parts of the air resistance are represented by the force system (3). The solution obtained contains: (1) A formula for lateral drift. (2) Formulæ for the vertical and lateral components of the yaw. (3) A formula for cross-range wind deflexion. The solution is valid provided the yaw and the inclination of the axis of the shell to the plane of fire do not become too great, and it exhibits the well-known properties of the phenomena of drift.—A. L. **Narayan** and D. **Gunnaiya**: Absorption of lithium vapour. Absorption of the lithium vapour in the visible region has been studied. The vapour possesses channelled absorption spectrum both on the short and the long wavelength side of the first member of the principal series.

PARIS.

Academy of Sciences, June 10.—M. Guillaume Bigourdan in the chair.—A. **Haller**: The action of tetrachlorophthalic and tetrabromophthalic acids on turpentines. A new method of preparation of the camphols and therefore of the lævo- and dextro-camphors. The interaction of the tetrahalogenophthalic acids and pinenes gives bornyl, isobornyl and fenchyl tetrahalogenophthates, which by saponification give mixtures of these alcohols and their acid esters. The alcohols thus formed give fenones or camphors according to the terpene employed.—Charles **Rabut**: The scientific rules to be followed in structures of armoured concrete.—M. de **Sparre**: Pelton turbines working under a variable head.—J. Kampé de **Fériet**: A particular class of hypergeometrical functions of one variable.—Georges J. **Rémoundos**: The pairs of meromorp or algebroid functions corresponding to the points of an algebraic curve.—Octave **Mayer**.—A geometrical interpretation of the second fundamental quadratic form of a surface; in relation with the theory of parallelism of Levi-Cività.—P. **Dumanois**: The use of light alloys for the pistons of internal combustion motors.—A. **Barbaud**: Tracing lines of height and its application to aerial navigation over the sea.—T. **Peczalski** and A. **Launert**: The electrical resistance and density of copper cemented by salts.—P. **Bovis**: The absorption spectrum of bromine. The maximum absorption corresponds sensibly to the same wavelength for liquid bromine as for its vapour; but, calculated to the same weight of bromine, the maximum values are

different, the optical density of the liquid being more than double that of the vapour.—M. **Duffieux**: The origin of the first and second positive group of the band spectrum of nitrogen.—H. **Chipart**: The electromagnetic theory of optical activity and the postulate of MacCullagh.—H. **Pélabon**: The direct formation of the oxychlorides, oxybromides, and oxyiodides of mercury. Mercuric chloride, bromide, and iodide can unite directly with yellow or red mercuric oxide, dry or in the presence of water. In the last case the equilibrium is affected by alkali dissolved from the glass containing-vessel.—Stefan **Triandafil**: The influence of temperature on the galvanic polarisation of nickel.—René **Dubrissay**: The capillary phenomena which appear at the surface of separation of water and benzene in the presence of the fatty acids and of alkalies.—Francis **Perrin**: The law of decrease of the fluorescent power as a function of the concentration.—E. **Darmois**: The compounds of malic acid and copper. Measurements of the P_H and rotations of solutions of copper hydroxide in malic acid indicated the presence of two malates only, the acid salt and Liebig's basic salt.—M. **Bourguel**: The transformation of the substituted acetylene hydrocarbons into true hydrocarbons by sodium amide. Hydrocarbons of the type $RC{\equiv}C.CH_3$ are readily transformed by heating with sodium amide at 110° C. into hydrocarbons of the type $(CH_3)R.C{\equiv}CH$. The homologues $RC{\equiv}C.C_2H_5$ undergo a similar change, but much more slowly.—A. J. A. **Guillaumin**: The action of hydroxylamine on ethyl tartrate.—Alphonse **Mailhe**: The decomposition of chlorophyll extracts. Distilled with magnesium or zinc chloride, these extracts give a gas rich in carbon dioxide, a mixture of liquid hydrocarbons containing a high proportion of olefines, and a solid, probably dinonylketone $(C_9H_{19})_2CO$.—P. **Lasareff**: The mass of metallic iron contained in the ferruginous deposits at Koursk (Central Russia).—Albert **Nodon**: Observations on the propagation of the explosive waves resulting from the experiments at La Courtine. Details of the methods employed to measure the velocities of the air waves and earth waves caused by the explosions at La Courtine, distance 243 kilometres.—P. **Gillot**: Remarks on the determinism of sex in *Mercurialis annua*. Supplement to NATURE

No. 2853 JULY 5, 1924

Insulin.[1]

By Prof. Hugh MacLean, Professor of Medicine, University of London.

NO recent discovery in medical science has created so much interest, both in lay and in professional circles, as the advent of insulin. The great importance of this discovery lies in the fact that through its agency a fresh outlook and a new hope have been opened up to the unfortunate sufferer from diabetes—an outlook in which despair and the prospect of almost certain death have given place to health and hope. From the humanitarian point of view, this itself is no mean achievement, but insulin has many interesting features besides its success in therapeutics, and the problem of its method of action presents an intellectual puzzle, which, from its complexity and obscurity, bids fair to engage our ablest scientific minds for many years to come.

Before discussing the results obtained from the use of insulin in diabetes, it is essential that certain points bearing on the metabolism of our foodstuffs should be clearly understood, for diabetes is nothing more than an interference with the normal mechanism which burns up our food in the body. Unlike the healthy individual, the diabetic subject cannot utilise his food, and, in consequence, becomes thin and ill. He presents the curious anomaly that the more food he eats the thinner and weaker he becomes, for, as the result of the perverse process of metabolism from which he suffers, much of the food that he is unable to use is changed into poisonous bodies which circulate in the blood, and cause destruction of body tissue, soon to be followed by death.

Though one of the most important symptoms of diabetes is glycosuria, or the presence of sugar in the urine, it is important to appreciate the fact that diabetes is a disease not of sugar or carbohydrate metabolism alone, but that the metabolism of all our foodstuffs is involved.

Metabolism of Foodstuffs in the Body.

Our knowledge of the various changes which the different foodstuffs undergo in the body is unfortunately very meagre, but we know sufficient to enable us to understand the main points in diabetes. Our food consists largely of starchy material or carbohydrate, with a certain amount of fat, and a fair proportion of such products as meat, fish, eggs, and other related bodies known as proteins.

Fats and carbohydrates are used simply as fuel for the body, and as the result of their combustion, heat and energy are generated. Both ultimately produce end-products which are removed from the body largely in the expired air as water and carbon-dioxide. Proteins also supply heat and energy, but they are used for another purpose as well; they form the bricks for building up the waste tissues of the body. That part of the protein molecule which is not required for the renewal of waste tissue is utilised for the production of heat and energy, just as in the case of fats and carbohydrates.

If we endeavour to follow the course of carbohydrate metabolism in the body, we are at once presented with many difficulties, but a few main features are fairly clear. It is certain that starch, no matter in what form it is taken in, is broken down in the intestinal canal by enzyme action into the simple sugar known as glucose. This glucose is then absorbed into the blood, and before getting into the general circulation, passes through the liver. If a great deal of glucose is present, the liver stores part of it for future use, and thus prevents an excessive amount of glucose from being present in the blood at one time. The storage substance which the liver forms from glucose is a starch-like body known as glycogen. Though the chief depot for glycogen is the liver, a good deal is found in the muscles as well. This glycogen is gradually converted into sugar again in response to the requirements of the body, so that a certain amount of sugar is always available for oxidation by the tissues. There is now a good deal of evidence that another storage product besides glycogen is formed during sugar metabolism—the lactacidogen of Embden—but it is doubtful whether this substance, which appears to be of the nature of a compound of sugar and phosphoric acid, ever gives rise to sugar again in the muscles after it is formed. When sugar reaches the tissues it is burnt up and forms carbon-dioxide and water. Many investigations have been carried out in an endeavour to find the intermediate substances between these end products and the larger sugar molecule, but of this phase of metabolism we know nothing with certainty.

Fat is also acted on by the intestinal juices and absorbed as free fatty acids and glycerin; it is largely stored as fat in the body. Before final oxidation, fat is broken down into a lower four-carbon fatty acid—oxybutyric acid—together with diacetic acid and acetone. These substances are then oxidised, forming the usual end-products, carbon-dioxide and water.

It is probable that both fat and carbohydrate have a definite and separate mechanism for metabolism, but that protein, on the other hand, does not possess a separate mechanism. When tissue waste is restored, the remaining protein is broken down into substances similar in nature to the intermediate products of sugar and fat metabolism, which are probably oxidised by the same mechanism as is used for fat and carbohydrate.

[1] Discourse delivered at the Royal Institution on March 28.

Metabolism in Diabetes.

In diabetes the carbohydrates are as usual hydrolysed to glucose in the intestinal tract, but after absorption the glucose tends to accumulate in the body, with the result that a certain amount of it is excreted in the urine. This excess of sugar in the body in diabetes depends on two causes. In the first place, the liver and muscles are unable to store the excess of sugar as glycogen, while in the second place, the tissues have lost to a great extent the power of oxidising sugar. The consequence is that a great deal of glucose is always present in the blood, resulting in a great waste of sugar through the kidneys. It is an interesting fact that one of the earliest manifestations of diabetes appears to be a lack of power on the part of the liver to store sugar as glycogen. This difficulty may be in evidence long before any symptoms of diabetes manifest themselves. In severe cases, oxidation of the sugar is also markedly interfered with, a phenomenon which depends on a lesion of the pancreas; this defective oxidation is most marked in the later stages of very severe diabetes. Generally speaking, sugar passes into the system of the diabetic and is largely passed out again without being utilised. Why this should be so is at present unknown, though various suggestions have been made.

The chemical researches of Fischer and of Irvine have demonstrated the existence of a more active form of glucose than the ordinary variety found in diabetic urine, and it has been surmised that this more active γ-glucose might be the form which the body requires for metabolism. If the body can utilise glucose only after it has been changed into the more active form, it is obvious that a defect in the mechanism responsible for this change would result in a condition similar to what we have in diabetes. The body would be supplied with a variety of sugar which it could not metabolise, with the result that this sugar would be excreted in the urine like any other foreign body. Attractive as this theory appears, it must be admitted that, so far, no convincing evidence of the existence of γ-glucose in the body has been advanced.

With regard to the metabolism of fat in diabetes, it appears that the breaking down of the large fatty acid molecule goes on as usual to the stage of ketone bodies, but that these bodies fail to be oxidised; they therefore accumulate in the blood and are largely excreted in the urine.

As already explained, the oxidation of protein probably takes place partly along the path of carbohydrate metabolism, and partly along the path of fat metabolism. The result is that protein may give rise to both sugar and ketone bodies in the diabetic urine, about 60 per cent. of the amino acids of protein being capable of forming sugar, while 40 per cent. may be excreted as ketone bodies.

The total result of these changes in metabolism is that the urine of the diabetic subject frequently contains large amounts of glucose together with oxybutyric acid, diacetic acid, and acetone.

The diagram (Fig. 1) indicates roughly what happens in metabolism in both the normal and diabetic person. These observations make it clear that no change in the particular class of food-stuffs taken will necessarily result in the elimination of sugar and ketone bodies from the urine.

Blood Sugar Changes in the Normal and in the Diabetic Subject.

Some knowledge of the physiological changes which the blood sugar concentration undergoes in the body is essential in the study of diabetes. In the normal subject, when the blood is examined two or three hours after a meal, it is found to contain about 0·1 per cent. of glucose. As a rule the blood sugar does not sink appreciably lower than this in ordinary circumstances. After the ingestion of carbohydrate food, however, it rises to a maximum of about 0·16 to 0·18 per cent. and then quickly falls to the former level of about 0·1 per

cent. Usually the maximum rise takes place within one-half to three-quarters of an hour after a meal, and generally the blood sugar content is found to be normal in about one and a half to two hours. These changes are best observed after a meal consisting of from forty to fifty grams of glucose. It might be thought that the early rise just described is due simply to increased absorption of sugar into the blood and that the fall towards the normal level merely indicates that absorption is complete. This is by no means the case, as can easily be shown by experiment. Indeed, it would seem that absorption of sugar may be going on just as rapidly after the blood sugar falls to the normal level as it was when the blood sugar was at its maximum.

The explanation of the phenomenon appears to be that, after some absorption of sugar into the general circulation has taken place, a special mechanism comes into action which stores the sugar as glycogen and so reduces the amount in the blood; this mechanism

resides chiefly in the liver. In connexion with this storage action it is interesting to observe that it is generally quite impossible to raise the blood sugar concentration beyond 0·18 per cent. or so. No matter how much sugar is taken, no greater quantity than this will be found in the blood. Whenever the concentration reaches this point, the liver storage mechanism becomes so strongly developed as to prevent any further rise. The interest of this observation lies in the fact that whenever the blood sugar rises above 0·18 per cent., the kidney begins to excrete sugar in the urine. Until this concentration is reached no sugar is excreted. The difficulty of raising the blood sugar beyond 0·18 per cent. or so indicates that glycosuria in the normal subject should be very difficult to produce as the result of ingesting large amounts of sugar, and experiments show that no sugar appears in the urine of the healthy subject however much sugar he eats.

From these statements it will be clear that the presence of sugar in the urine indicates that the blood sugar concentration is in the region of 0·18 per cent. or higher. Though the normal kidney does not excrete sugar until this concentration is reached in the blood, it sometimes happens that the kidney may leak and allow sugar to pass into the urine when the concentration in the blood is much lower than the figure given. This condition, which is fairly common, is known as renal glycosuria ; obviously it has nothing whatever to do with diabetes. It gives rise to no symptoms and produces no bad effects.

In diabetes the glycosuria is always due to an increased amount of sugar in the blood—a hyperglycæmia—and the changes in blood sugar concentration after eating starch or sugar are very different from those in the normal subject. If fifty grams of glucose are given to a diabetic subject, the rise in blood sugar is much higher than in the normal, and it continues high for a much longer period. Generally, of course, it happens that the blood sugar in the diabetic is much higher to begin with than it is in the normal subject, but it may often be reduced by appropriate dieting to the region of 0·1 per cent., and when this is done and sugar is taken, the blood sugar soon shoots over the 0·18 per cent. mark and often reaches 0·3 per cent. or more, at which high level it may remain for hours. The curves in Fig. 2 represent the effect of 50 grams of glucose on the blood sugar of a normal and a diabetic subject. It is interesting to note that the only sugar which does not raise the blood sugar in the normal subject is lævulose ; in the diabetic, however, lævulose acts just as any other sugar. An appreciation of these facts is necessary in order to understand the action of insulin.

Glycosuria not Diabetes.

Though glycosuria constitutes an important symptom of diabetes, it must be clearly understood that the finding of even large amounts of sugar in the urine does not necessarily mean that diabetes is present. When glycosuria results from a leakage of sugar through the kidney, the condition is obviously of little or no importance, as already explained. Temporary glycosuria is not infrequently produced as the result of such conditions as mental excitement and fear. The explanation that has been suggested by physiologists to account for the increase of blood sugar caused by fear, is, that under primitive conditions some degree of fear was generally a preliminary to active muscular exertion of a defensive nature, and that the sugar was provided as fuel for the production of the required energy. Again, it is very common to find sugar in the urine of students after an examination. An interesting observation bearing on this point was reported some years ago by certain American observers. They examined the urines of a number of male students after an examination and found sugar in 18 per cent. of them. On extending the experiment to female students, contrary to expectation, no such result was in evidence, but since these latter students were all much younger than the males, it is probable that the irresponsibility of youth rather than any fundamental lack of emotion

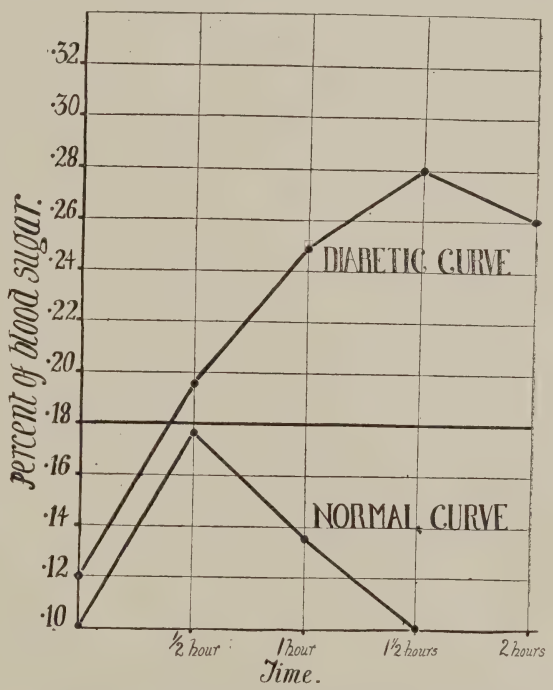

Fig. 2.—Curves of blood sugar concentration obtained from a normal and a diabetic subject after giving each 50 grams of glucose by mouth.

was the cause of the difference. Glycosuria also appears as the result of taking various drugs, and is not very uncommon in elderly patients who practise the belief so widely prevalent that rejuvenation and restoration of bodily and mental vigour may be obtained by the ingestion of large amounts of thyroid gland extract. Another cause of glycosuria not infrequently encountered is the excessive use of alcohol. After long dinners in which alcohol may play but a moderate part, glucose is frequently found in the urine on the following day. All these conditions are dependent on a temporary hyperglycæmia, but they disappear whenever the condition giving rise to them is removed. This glycosuria must not be regarded as of a diabetic nature.

Chief Symptoms of Typical Diabetes.

Along with the blood and urine changes described above, the diabetic suffers from general weakness,

marked emaciation, great mental depression, thirst, hunger, and a very great tendency to the onset of a most serious condition associated with drowsiness and ultimately resulting in unconsciousness and death; this latter state is the fatal condition known as diabetic coma. It is liable to appear sooner or later in every case of severe diabetes, and apart from accidental complications, is the usual cause of death in the diabetic subject.

Though this is the general course in typical diabetes, it must be admitted that the progress of the malady varies much in different individuals, and that many varieties of the disease, from a chronic slowly progressive type to what might almost be called fulminating diabetes, are encountered. Before the advent of insulin it was quite the exception for a patient suffering from well-marked diabetes to live for more than five or six years, though sometimes this period could be extended by careful dieting. This class of case is easily recognised and represents typical diabetes mellitus.

Another variety of so-called diabetes is by no means uncommon in middle-aged and elderly individuals. The patient may feel quite fit, or more frequently he complains of being somewhat out of sorts, with weakness of the limbs and a feeling of tiredness and lack of energy. On examination of the urine a large amount of sugar is found, but no ketone bodies are present. Unlike the true diabetic, there is no emaciation; indeed such a patient frequently tends to get excessively fat. The presence of this condition is not incompatible with the enjoyment of more or less good health for very many years during which sugar is continually passed, and frequently there does not appear to be any progressive tendency on the part of the disease. In such cases there is no danger whatever of coma intervening, and it is obvious that the condition differs essentially from that of true diabetes. Indeed, the patient is not really suffering from diabetes at all, but from a well-marked and persistent glycosuria; his urine contains none of the toxic metabolic products characteristic of diabetes.

What happens in this type of case is that the liver has to a large extent lost the power to store sugar as glycogen, with the result that there is constantly a more or less excessive amount of sugar present in the blood, giving rise to glycosuria. Unlike what occurs in true diabetes, where a definite defect in the pancreas is present, there is here apparently no difficulty in oxidising sugar or fat in the tissues, hence the absence of ketone bodies in the urine. The constant excess of blood sugar probably stimulates the pancreas to produce more insulin, with the result that a good deal of this sugar is stored as fat in the same manner as the diabetic patient treated with insulin tends to put on fat. Occasionally, though not very frequently, this type of persistent glycosuria develops after many years into a true diabetes. This somewhat rare contingency appears to depend on the fact that the large amount of blood sugar constantly present stimulates the pancreatic cells to an over-activity which sometimes results in exhaustion. While true diabetes is probably always associated with a pancreatic lesion, the type of so-called diabetes just described appears to be dependent on a disturbance of the liver. Though, in true diabetes, the liver also fails to store sugar, yet this is but one part of the condition; the most important point is that oxidation of sugar and other foodstuffs is defective. In the glycosuria of elderly individuals the defect appears to be limited to the liver.

The Cause of Diabetes.

The older observers appear to have been impressed by the frequency with which patients dying from diabetes showed definite lesions in the pancreas, and the older literature contained many statements emphasising this point. It was not, however, until 1889 that the relationship of the pancreas to diabetes was definitely established. In that year, von Mering and Minkowski, in an epoch-making paper, showed that the removal of the pancreas from an animal resulted in a condition which was practically the same as severe human diabetes. Removal of part of the gland might or might not produce glycosuria according to the amount of healthy tissue left behind, but complete extirpation was followed in every case by intense symptoms and a fatal termination in coma within a few weeks. Evidence was obtained that this result was not dependent on the loss of the ordinary pancreatic tissue, and it is now generally accepted that certain small islands of special cells found in the pancreas—the Islets of Langerhans—are connected with carbohydrate metabolism and that their destruction or removal results in diabetes. These important experiments constitute the foundation on which all subsequent advances in our knowledge of diabetes, including the discovery of insulin, are based.

Attempts to obtain Pancreatic Extracts for the Treatment of Diabetes.

The discovery that destruction or removal of the pancreas in animals gave rise to diabetes at once suggested the idea that this disease might be successfully treated by giving pancreas or pancreas extract to the patient. It was obvious that the pancreas must contain some active principle which was necessary to prevent diabetes, and the natural inference was that if this substance could be supplied to the diabetic, the symptoms of diabetes would disappear. At first, fresh pancreas or various extracts of the gland were given by mouth, but without any apparent effect. Later, various special preparations were tried by injection, but the results, though by no means always negative, were variable and unsatisfactory. It may with confidence be said that practically every investigator interested in diabetes has at some time or other tried the effects of pancreatic extracts.

It soon became clear that no effect whatever was produced when the preparations were given by mouth, but several observers had quite marked results when hypodermic or intravenous administration was used. Thus, for example, Zuelzer in 1908 prepared an extract which he injected into diabetic patients, with the result that, though no change was made in the diet, the sugar and ketone bodies previously present in the urine were much reduced or, indeed, in some cases disappeared altogether. At the same time the patients improved in general health. The method was, however, given up on account of the frequency with which injections were followed by more or less serious disturbances in the patients, some of whom became very ill, while others showed high fever, rigors and prostration. Zuelzer's product was prepared from the pancreas by

the use of alcohol. He assumed that the active principle was easily destroyed by the pancreatic ferment, and took the view that this might be prevented by treatment with alcohol. Later, Scott, working in America on somewhat similar lines, obtained a preparation which was definitely active though rather weak and inconstant. Various observers had somewhat similar experiences, but nobody was able to prepare a trustworthy non-toxic substance for clinical use in diabetes, and a few years ago it seemed as if the problem was insoluble. The disappointing results of so many investigators tended to substantiate the impression that further work on the problem was not likely to produce results, and our earlier hope of being able to treat diabetes successfully by pancreatic extracts had to a large extent vanished.

This was really the position when Banting took up the subject. Banting adopted the view propounded by many earlier investigators that the trypsin of the pancreas destroyed the internal secretion or hormone necessary for normal carbohydrate metabolism, and that the failure to obtain an active substance depended on this digestive action of trypsin. The difficulty was to devise some means by which this destructive action of trypsin during extraction of the pancreatic tissue could be avoided. It was well known to physiologists that the ordinary pancreatic tissue which secretes enzymes for the digestion of food underwent degeneration after ligature of the pancreatic duct, while on the other hand the islets of Langerhans were not affected. Banting therefore tied the duct in an animal and after several weeks removed the degenerated pancreas. If the theory mentioned was correct, an extract of this pancreas should contain an active substance for the treatment of diabetes since no digestive enzymes would be present. This actually proved to be the case, for a simple saline extract of this pancreas when injected into a diabetic animal lowered the blood sugar and reduced the amount of sugar passed in the urine.

This result was exceedingly interesting, but its practical application on a large scale was obviously impossible. Fortunately, however, it was soon found that the initial tying of the duct was unnecessary, for further experiment on the lines of Zuelzer's work showed that quite active preparations could be obtained from the normal pancreas. Ox pancreas was macerated as soon as possible after the death of the animal and left standing for several hours in 95 per cent. alcohol. The mixture was then filtered and the clear fluid obtained evaporated to dryness by means of a current of warm air. The residue was then dissolved in saline and used for injection. To this active substance Banting gave the name "Insulin."

It is not quite certain whether Banting's original view is correct, but this is of little importance from the practical point of view. Banting's success was largely dependent on the ease with which blood sugar can now be estimated, for it was essential in judging of the effect of insulin on animals that blood sugar estimations should be carried out at frequent intervals. Some years ago this was practically impossible, but now blood sugar may be estimated in the same animal every few minutes if necessary. To Banting belongs the credit of having prepared an active extract of pancreas suitable for the treatment of diabetes, but it must not be forgotten that this great achievement was rendered possible only by the laborious work of many earlier observers. Banting's final triumph was no doubt largely brought about as the result of modern developments in biochemical methods, but, taking everything into consideration, it still remains a mystery why insulin was not isolated many years ago.

As was the case with all former investigators, Banting's earlier products frequently gave rise to more or less alarming symptoms when injected into patients, so attempts were made to obtain a purer substance. These attempts were successful, and samples of insulin were soon prepared which possessed little or no toxic effects. The present method of manufacture depends on the isolation of a crude product by fractional precipitation of pancreatic extract with alcohol; this impure body is treated with picric acid, and insulin picrate precipitated, from which a fairly pure substance suitable for clinical work is obtained. This method requires the use of large amounts of alcohol and is somewhat tedious and expensive; also, it takes several days to complete the extraction and preparation of the insulin. Quite recently, Dodds, at the Middlesex Hospital, worked out a process for the isolation of insulin which possesses many advantages over the usual method in vogue. The principle of this method is based on the earlier observation by Dudley, that insulin could be most conveniently separated as the picrate. In the modification suggested by Dodds, the fresh pancreas is thoroughly ground up with solid picric acid, thus converting the insulin directly to picrate and so reducing the time during which tryptic action may occur. By this process the old tedious filtration of the alcoholic extract is rendered unnecessary. The pancreas-picric acid creamy mixture is treated with acetone, which dissolves out the insulin picrate. The picrate is then purified on the usual lines. Not only is this method more expeditious, but also it actually gives a higher yield of insulin.

Standardisation of Insulin.

The effect of insulin in reducing the blood sugar is not confined to diabetic animals, for it reduces the blood sugar of normal animals as well. This effect of insulin is used in the standardisation of the product for clinical use, and the present unitage is based on the dose required to reduce the blood sugar of a normal rabbit to about 0·04 per cent. An average dose for a diabetic patient is 10 units, but the amount given depends on the gravity of the condition.

Symptoms produced by Insulin.

In both the normal and the diabetic individual, insulin may produce definite symptoms when given in excess. The chief of these symptoms are hot flushes especially on the face, weakness of the limbs, giddiness, sweating, tremulousness, and ultimately, if the condition is not relieved, convulsions, coma, and death. This property of insulin makes the remedy a very dangerous one unless great care is used in its administration, and no doubt explains many of the difficulties encountered by the earlier investigators.

The occurrence of these clinical phenomena is associated with the action of insulin in reducing the blood sugar. When the blood sugar gets too low, the fact

is indicated by the appearance of these symptoms, but it is now certain that patients differ greatly as to the exact blood sugar concentration that may be present when the symptoms come on. Taking the normal resting sugar as about 0·1 per cent., it would seem that in certain subjects, even a slight decrease to about 0·08 per cent. or so may be associated with insulin symptoms, while, in others, the blood sugar concentration may be so low as 0·05 per cent., and yet the patient may feel quite well. In a general way, it is now established that the train of symptoms induced by insulin do not appear when the blood sugar is normal or above this level, but that they are liable to manifest themselves whenever the blood sugar sinks to a sub-normal value; the exact level at which they appear depends on some unknown factors present in the patient. The association of these insulin symptoms with a more or less lowered blood sugar concentration—a hypoglycæmia—is, however, so pronounced that they are generally referred to as hypoglycæmic reactions. It may be taken for granted that when insulin symptoms do come on, the lower the blood sugar the more severe are the symptoms likely to be. Fortunately, these symptoms are very soon relieved if some glucose is taken, so that, generally, this insulin hypoglycæmia is not dangerous, provided that the patient is warned as to the nature of the symptoms, and takes glucose immediately they come on. In certain circumstances, however, the condition may be a very real danger, as every one who has treated many patients must have found.

The curious variation to the influence of insulin which exists in normal individuals is well shown by the results of an experiment carried out in my laboratory on two young healthy medical men each about the same build, age, and weight. For a day or two before the test, both subjects took the same amount and the same kind of food. On the morning of the experiment each received 50 grams of glucose by mouth, and shortly afterwards 20 units of insulin were injected hypodermically. Samples of blood were then taken at frequent intervals for blood sugar estimations. One subject showed no symptoms whatever after the insulin, while the other developed symptoms so severe that it was difficult to get blood for sugar estimations. A further 50 grams of glucose given by mouth had a marked but only a temporary effect in relieving these symptoms, so that very soon the condition was as severe as before and indeed somewhat alarming. A further 60 grams of glucose was then administered with the result that the insulin phenomena passed over once again, though some slight symptoms reappeared later. So far as blood sugar concentration was concerned, there was little difference between the subjects; in both the blood sugar fell to the region of 0·07 to 0·08 per cent. The description of his symptoms given by the subject who suffered from insulin symptoms was as follows: "The first noticeable symptom was profuse sweating of the face, scalp, and neck. This was very quickly followed by inability to perform fine movements with the hands, and weakness of the legs, which, however, was only noticed when standing up. General symptoms were dizziness, and an impression as of all near objects being far away and having a swaying movement. On recovery after glucose, the sweating, dizziness, and swaying sensations were the first to go; the sense of weakness in the limbs remained for the longest time."

In the treatment of insulin hypoglycæmia, there is no difficulty in administering sugar provided the patient is still conscious; on the other hand, when the patient is unconscious, it may be very difficult indeed to get sugar into the system. In such cases the patient may generally be brought round by the injection of 1 c.c. of 1 in 1000 adrenalin solution. A dose of pituitrin (1 c.c.) given subcutaneously will also produce the desired result. If, however, consciousness is not soon restored by these methods, glucose must be injected into the circulation through a vein. This procedure never fails to bring the patient round, provided the hypoglycæmic condition has not lasted too long.

Though severe hypoglycæmic phenomena with unconsciousness were observed fairly often some time ago when our knowledge of the action of insulin was very limited, they are very seldom encountered at the present time, and should never ensue when the use of insulin is founded on a correct perception of its action and properties.

The Use of Insulin in Diabetes.

From what has already been said, it is obvious that insulin does not cure diabetes. Insulin merely replaces a missing substance in the body of the diabetic, and so long as a suitable dose of insulin is being administered, the patient is free from symptoms and feels well both physically and mentally. When the administration of insulin is stopped, the old symptoms reappear. In a typical case of diabetes the results produced by insulin are frequently dramatic. From being a weak, depressed, emaciated wreck, the diabetic very soon becomes a strong, energetic individual. The sugar and ketone bodies disappear from the urine, and there is nothing to indicate that the patient had ever been the subject of diabetes.

Suggestions have been brought forward in some quarters that the vigorous use of insulin may so rest the pancreas that a great improvement in tolerance may be established, and that in some cases a cure may be effected. In my opinion, there is no basis for this expectation, and it is unlikely that insulin will do more in this direction than will a carefully regulated diet. There is a feeling among the public that once insulin is used, it must be administered permanently, for it is believed that the condition of the patient who stops taking insulin is worse than if he had never begun it. This, however, is not so, for a patient may cease to take insulin and be no worse than he was before. Insulin is given by hypodermic injection, the average dose being from 10 to 20 units twice daily. It is usually injected about a quarter to half an hour before food, and is given in the morning and at night, before breakfast and dinner respectively.

One of the most important points in the use of insulin is that the diet should be carefully correlated with the insulin dosage. As a rule, one unit of insulin will "look after" about two to three grams of carbohydrate, so that it becomes most important that an excessive amount of food should not be taken. It is just as necessary for the patient on insulin to follow definite rules as regards food, as it is for the diabetic patient who is being treated by diet alone. The only

difference is that the insulin patient can take a more liberal diet. Once the diet is fixed, it must be adhered to, for a difference in diet would necessitate a difference in dosage of insulin, with the result that at one time the patient might be passing large amounts of sugar, while at another time the insulin might be in excess in relation to the diet, and the patient might suffer from the insulin symptoms already described. I have seen a patient who was taking a fairly large dose of insulin (20 units twice daily), but paying no attention to his diet, pass into diabetic coma.

Insulin and Pancreatic Preparations given by Mouth.

Insulin has practically no effect in lowering the blood sugar when given by mouth; the reason for this is that insulin is very easily destroyed by the ferments present in both the stomach and intestine. These ferments produce their injurious action very rapidly, so that insulin is destroyed before it can be absorbed. Various attempts have been made to give insulin by mouth in association with some substance known to undergo very rapid absorption, and, in this connexion, claims have been put forward that when insulin is taken in alcohol a fair amount of it is absorbed and produces, to some extent, its usual effect of lowering the blood sugar. These claims, however, have not been generally substantiated.

At present there are numerous pancreatic preparations on the market for which the claim is advanced that when taken by mouth they relieve the symptoms of diabetes. It is not always quite clear whether the vendors of these preparations claim that their products contain insulin, but since insulin is destroyed in the alimentary tract, it is obvious that any such claim is of no importance, for even if these preparations did contain insulin, they would be of no therapeutic value when taken by mouth. It is conceivable, however, that pancreatic preparations given by mouth might exert a beneficial action on diabetes apart altogether from the action of insulin. With the view of investigating this point I have tried nearly all the well-known preparations of this kind on the market. So far as my observations go, it would seem as if all these products given by mouth are of no value whatever in the treatment of diabetes.

Some Difficulties accompanying the Use of Insulin.

Naturally, the injection of insulin two or three times a day causes some physical discomfort, but when sharp fine needles are used this is not an important feature, and patients do not mind the slight pain of the injection. Sometimes there is a definite local reaction which may give rise to marked swelling and redness at the site of injection. This reaction generally persists for about twenty-four hours, after which it gradually disappears. As more experience in the manufacture and purification of insulin is gained, these local reactions appear to be less and less frequently encountered, and at the present time no great amount of trouble is experienced on this account. Sometimes, especially during the early stages of insulin treatment, the legs begin to swell somewhat, but this soon disappears.

Continuous administration of insulin over long periods tends to produce a hardening of the skin around the site of injection, so that after some months, a large area of the arm or leg may be markedly indurated. By varying the site of injection, and using different parts of the body, this difficulty may be largely overcome. It must be admitted, however, that the continuous administration of insulin to children is not always an easy problem, for the available surface for injection is not very large, and the skin of both arms and legs sometimes becomes so hard that it is difficult to insert the hypodermic needle. It is usually found that adult patients can inject themselves quite satisfactorily. On the whole, injection of insulin when carefully done does not give rise to so much difficulty as might perhaps be expected, but, on the other hand, there is no doubt that the advent of an effective preparation that could be given by mouth would be a very great practical advance in diabetic therapy.

Diet in Insulin Therapy.

In order to obtain the best results from insulin, it is necessary to put the patient on a special diet containing but a small amount of carbohydrate, the rest of the diet being made up of protein and fat. The amount of food required by a diabetic patient varies according to many conditions such as age, weight, and the amount of work done. It is now customary to express dietetic values, not by the weight of material consumed, but in terms of heat value or calories.

For practical purposes it may be accepted that 1 gram of protein or 1 gram of carbohydrate is equivalent to 4 calories, while 1 gram of fat is equivalent to 9 calories. Now a patient requires roughly a diet that will contain from 10 to 15 calories for each pound he weighs. Thus a patient weighing 140 pounds would require a diet containing from 1400 to 2000 calories, or he would probably do quite well on a diet containing about 1700 calories. In ordinary circumstances, he would no doubt consume considerably more than this. It is essential that the diet should contain some protein, and 0·5 gram or somewhat less for each pound the patient weighs is generally required. Since the carbohydrate allowance is necessarily small, insulin diets usually contain a fairly large amount of fat. Carbohydrate should, if possible, be given in moderate amount, for it ensures safety in the use of insulin, especially during the earlier stages of treatment, and makes the diet more palatable.

Prevention of Insulin Symptoms.

Since insulin symptoms do not come on until the blood sugar is reduced considerably below 0·1 per cent., it follows that no such symptoms are ever in evidence so long as the diabetic passes even a very small amount of sugar in his urine. Some medical men give just sufficient insulin to keep the urine almost but not entirely free from sugar, and thus guard against the onset of any insulin symptoms. Where facilities for blood sugar estimations are available, it is best, however, to give sufficient insulin to reduce the blood sugar to about the normal level.

Though some failures in the use of insulin have been recorded, it is my experience that this remedy never fails to act in typical diabetes; whereas, if the patient is suffering from some other malady as well as diabetes, good results cannot always be expected.

Mode of Action of Insulin in Diabetes.

Insulin very soon reduces the blood sugar in diabetes and eliminates glycosuria even in some patients when comparatively large amounts of carbohydrate food are taken. Strange as it may seem, it appears to be definitely established that the sugar which disappears from the blood as the result of insulin injection does not form glycogen. In rabbits fed on carbohydrate and treated with insulin, little or no glycogen is present, while in well-fed ordinary rabbits not treated with insulin, large amounts of glycogen are found. It is, therefore, obvious that the carbohydrate metabolism of the normal individual may be different in degree at any rate from that which obtains in the patient whose metabolism is helped by the use of insulin.

One of the most impressive features of the insulin patient is the extreme tendency to put on fat. Experiment shows that the sugar which has disappeared does not form fat *directly*, though there is little doubt that it does so indirectly. If we accept the view, which appears to be fairly well established, that insulin does not form glycogen from sugar and does not *immediately* and *directly* form fat from sugar, we are confronted with the problem as to what does happen to the sugar. Increased combustion will not account for the disappearance, so part of it must be stored in some form in the body. There is a good deal of recent evidence that some of it, at any rate, is stored in the body as a combination of glucose and phosphoric acid—Embden's lactacidogen—for experiment seems to show that insulin increases the amount of this substance in the body. Very probably this complex represents an intermediate product on the way to fat formation. The problem of the action of insulin is, however, far from settled, for insulin has a profound effect on both fat and protein metabolism.

The Future of Insulin Therapy.

That insulin relieves the symptoms of diabetes there is no doubt whatever, but, unfortunately, its action is very liable to be interfered with by such causes as cold, an attack of influenza, a mild gastric upset, or almost any slight departure from normal health. The use of gas for removal of a tooth may cause a similar disturbance. In such cases, patients who were free from glycosuria and progressing satisfactorily may begin to pass large amounts of sugar in the urine, and may even suffer from marked diabetic symptoms. In these patients the dose of insulin must be very largely increased, but the correct dose may be difficult to determine. These interferences with the action of insulin render it necessary to keep patients treated with insulin under careful observation. Again, the fact that injection is necessary for the rest of the patient's life makes the use of insulin tedious and not altogether free from physical discomfort. It is difficult to contemplate children going on for forty to fifty years or more having two injections of insulin daily, and no doubt, in spite of insulin, many diabetic children will succumb to intermittent affections.

It is, of course, too early to say what the ultimate effects of insulin will be in the general treatment of diabetes. There is already a good deal of evidence pointing to the conclusion that some patients become, to some extent, accustomed to its action, so that larger and larger doses are necessary. This necessity for larger doses may only indicate a steady progression of the lesion, but a somewhat similar phenomenon is encountered in normal rabbits, which, when injected on several occasions with insulin, gradually show a markedly decreased response to each administration. Recently, some experimental evidence has been brought forward suggesting that, in normal circumstances, carbohydrate metabolism may be somewhat different from what it is under artificial insulin injection. Thus, when a dog is rendered diabetic by total removal of the pancreas, it is apparently impossible to prolong life *indefinitely* by the use of insulin, though, naturally, the dog can be kept alive by insulin for many months.

It might, therefore, be argued that there may be some cases of human diabetes comparable with the condition in the dog in which no active pancreatic tissue is present. In the ordinary diabetic subject there are, of course, some more or less active pancreatic islets left, and further, there is no evidence that the production of pancreatic digestive ferments is at all interfered with. In the depancreatised dog no pancreatic digestive ferments are present, and so intestinal digestion is markedly upset. It has, therefore, been suggested that the inability to prolong the life of the depancreatised dog indefinitely by means of insulin depends on the absence of digestive ferments, and chiefly on the inability to hydrolyse fat.

While this is a possible explanation, it does not seem to be a very probable one, for it has been shown that the depancreatised dog may apparently be kept alive indefinitely, provided a *very small part* of the pancreas is left behind. If these experiments are substantiated, it is not likely that the absence of digestive ferments plays much part in the depancreatised animal, for the amount of digestive ferment secreted by a very small piece of pancreas would scarcely be sufficient to influence the fat metabolism. Indeed, the evidence available at the present time points strongly to the probability that the pancreas forms another hormone essential for the process of normal carbohydrate metabolism besides insulin, and that unless this hormone is present, insulin alone will not sustain life for a long period.

From the clinical point of view, the above assumptions appear to be strongly borne out, and it appears certain that the use of insulin does not serve as a substitute for the normal mechanism. There are such marked differences between a normal individual and a diabetic under treatment with insulin that it is quite certain that the processes in the normal individual are in some way very different from those occurring in the diabetic individual. On the whole, so far as our present experience goes, it would appear that the average human diabetic patient can be kept alive for long periods by the use of insulin, so that, in the absence of accidental circumstances, the diabetic on insulin treatment may expect to live to a normal average age.

Great as have been the results obtained by insulin therapy, it has not yet provided a substitute for the normal process from the clinical point of view, and much has yet to be achieved. On the other hand, the marvellous success of insulin in the treatment of severe and otherwise hopeless cases of diabetes is one of the most striking triumphs in the whole field of modern therapeutics.

Europeans in the Indian Services.

THE story of the British servants of the Indian Government falls naturally into three periods. In the first period the Britisher (we cannot say Englishman because he was more often Scotch or Irish) usually gave up his native land, adopted India as his country, often took an Indian wife, and had a real chance of understanding the people he ruled. There were then few white women in India.

The transition to the second period was due to improved means of transport. The Britisher in the Indian Service no longer settled permanently in India, and he also normally brought with him a portion of European civilisation in the form of a wife. From the point of view of the welfare of India the change had a number of consequences. These British rulers were now birds of passage and thus had less opportunity and perhaps even less desire to understand the people. The introduction of European civilisation to India increased his separation from the people. The European wife disapproved of the earlier unions and their offspring, and the Eurasian, who might have continued to rank almost as high as the European if the first period had continued, now fell seriously in public estimation. Moreover, the presence of a wife and children was apt to affect the nerves of men who in their absence would have faced any situation with perfect equanimity ; the Mutiny still casts a shadow. But the greatest weakness (a weakness shared with the first period) was the absence of contact between the educational and political sides of the Government. On the educational side the Government was teaching the people respect and admiration for democracy, while on its administrative side it remained a benevolent despotism. So apt a pupil as the Indian could not be expected to refrain from a demand for democratic institutions ; which brings us to the third period.

The Morley-Minto reforms were not effectively in the direction of democratic government, and the third period dates from the Government of India Act of 1919 which gave effect to the Montague-Chelmsford reforms and introduced a degree of representative government under the system called "dyarchy." Under this system government activities fall into three classes :

1. Central services carried out for the whole of India by the Government of India.

2. Services entrusted to the local government acting on democratic lines, that is, entrusted to the governor acting on the advice of ministers responsible to a legislative council (called "transferred services").

3. Services entrusted to the local government on the old lines, the governor acting at his own discretion uncontrolled by the legislative council (called "reserved services").

The setting up of dyarchy inevitably raised certain problems, and it is the solutions to these problems offered in the report of the Lee Commission [1] that we have now to discuss. The problems were in effect (1) how should the staff required to carry out the transferred services be recruited and controlled, and (2) what proportion of Europeans should there be in the personnel of each of the services and how is the necessary number of suitable Europeans to be obtained. The principle of dyarchy gives the reply at once to the first question. The transferred services belong to the local government acting in its democratic capacity, that is to say, the officers are the servants of the legislative council, the orders of which they receive through the governor and ministers; and the appointment and control of the officers who carry out these duties must also be the affair of the governor and ministers acting for the legislative council. Accordingly the report proposes that for the education service, the agriculture service, the veterinary service, and the roads and bridges side of the engineering service, no new appointments should be made on the present terms on which officers hold from the Secretary of State, and that new services should be instituted to be recruited and controlled by the local governments.

Into the problem of the European recruits a number of considerations enter: the fall in the value of money, the question of security of tenure, the prospects of promotion, the comparison of the future and the past in regard to the spaciousness of the European's life, and the interest and importance of his work.

The proposals of the Commission in the matter of security and of the fall in the value of money are of a kind that should enable good men to undertake the work. The question of promotion depends on the relative merits of the European and the Indian in the services. The highest posts of all must be considered as outside the reckoning of the European because under the parliamentary system they will go more and more to Indians. Against this is to be set the fact that a smaller proportion of Europeans are to be recruited, so that the proportion of good posts per European is increased, and if they show themselves better men than their Indian colleagues their flow of promotion should be greater.

The greatest change is in the nature of the duties. The benevolent despot dislikes the change and thinks it will ruin India. He has ruled the Indians all his life on the assumption that they are children and he cannot now look on them otherwise. He is consequently out of place in the new system. Instead of him we need a man prepared to respect the Indian as an adult human being, to sympathise with his desire for parliamentary government, and to teach him to run the parliamentary machine. While this may be a position of less personal grandeur than the benevolent despot enjoyed, it is one of greater human interest, and for the right man it will provide a life fully as attractive as the old. It is also possible that by regarding the Indians as adults with human feeling and a certain degree of judgment, and not as children, the future European servants of the Government may escape from the shadow of the Mutiny which has so overhung their predecessors.

For the purpose of carrying out the recruitment and control of the services that are in the future to hold from the Secretary of State or the Government of India, a Public Service Commission is to be established. It will be both judicial and educational. Its judicial functions will be connected with the disciplinary control and protection of the services while its educational qualifications will come in in relation to recruitment. The appointment of this Commission is a necessary development and was in fact prescribed by the Government of India Act of 1919, and in addition to this central Public Service Commission each province will find it necessary to set up a similar body to manage the recruitment and control of the officers employed on transferred services. This is recognised by the Royal Commission, which states in paragraph 30 "we are aware that any proposal that a central Public Service Commission should be empowered to interfere on its own initiative in provincial administration would be regarded as violating the principle of provincial autonomy."

It is rightly recommended that the knowledge and experience of the Public Service Commission should be placed at the disposal of any local government that chooses to use it. It is highly desirable that the local governments should take advantage of this opportunity, but any self-respecting government will shy off if the attentions of the Public Service Commission are thrust upon it, and yet in paragraph 27(3) the Royal Commission recommends that the Public Service Commission should be the final authority for determining "the standards of qualification and the methods of examination" for the local government services. This recommendation clearly violates the principle of provincial autonomy and cannot possibly be put into force; and the very fact that it is recommended may determine the local governments to have nothing to do with the Public Service Commission.

The truth is that the Royal Commission has given little attention to the machinery of recruitment. Witness the illogical minute on the London Open Competitive Examination which has been thought worthy of publication. Witness also the recommendation that the upper limit of age for the Indian Civil

[1] Report of the Royal Commission on the Superior Civil Services in India, dated March 27, 1924.

Service should be twenty-four, because the universities prefer that age, and the statement that "it was a corollary of the decision to reduce the upper age limit to 23 years that the period of probation for recruits should be extended from one year to two"; the truth being that the basic decision was for two years' probation and reduction of the upper age limit to twenty-three an inevitable corollary. In this connexion we should have expected the Commission to take some account of the fact that a probation of two years is already in force for the Indian Civil Servants recruited in India.

In spite of these blemishes to which we have thought it necessary to direct attention, the fact remains that the Royal Commission has done sterling work towards making the government service attractive to the European. Its work is in the main excellent, and the blemishes can easily be removed.

Southern Nigerians.

Life in Southern Nigeria: the Magic, Beliefs and Customs of the Ibibio Tribe. By P. Amaury Talbot. Pp. xvi + 356 + 32 plates. (London: Macmillan and Co., Ltd., 1923.) 21*s.* net.

"ONLY by the good will of the black men will it ever be possible for more than the faintest idea of his complicated psychology to be grasped by the white; and could but the educated negro be brought to understand that he has infinitely more to gain than lose by recording every scrap of information concerning native customs and beliefs—omitting nothing and concealing nothing—such a book might be written as has never yet seen the light of day." This expression of opinion sums up Mr. Amaury Talbot's whole attitude towards the African. His latest book, "Life in Southern Nigeria," is written not only with knowledge and experience, but also in a spirit of sympathetic understanding. As a guide for future administrators the work is invaluable, combining as it does the results of scientific research with an appreciative knowledge of the beliefs and superstitions of an ancient people.

The Ibibio, of whom the author writes, are a little-known people living in the south-eastern part of Nigeria. They number, in all, more than a million, of whom some hundred and fifty thousand inhabit the Eket district. This is Mr. Amaury Talbot's description of them: "The Ibibio are typical negroes, thick set, with long arms, short trunks, medium-sized legs and feet broad and flat. Their language belongs to the Semi-Bantu group with many and strong affinities to the Sudanic tongue of their neighbours, the Ibo, with whom they have much in common." Although, as the author points out, the march of Western civilisation results in the younger members of the Ibibio becoming Christianised, many of the older generation still cling to beliefs and ways unchanged since the childhood of the world. "For them," he writes, "the commonplace does not exist, each object is tinged with wonder and mystery, while forces benevolent or malignant are to be felt on every hand."

According to Mr. Amaury Talbot there are two forces which influence the life of the Ibibio, the Ndemm (meaning fresh water) and the Ibokk (often translated by Juju as well as by medicine). The first of these forces dwells in or near rivers, pools, springs, and trees. They are gnomes, salamanders, dryads, etc., and are supposed to be male and female. The Ibokk are natural or elemental forces, which do not affect, or come into contact with, human beings until made to by a doctor or "wise" man. An interesting chapter is one on magic plays, where the author describes what may be called conjuring tricks. "A vast concourse of people gather together and a baby is brought into their midst. The child is thrown into a fu-fu mortar and beaten to pulp before the eyes of all the people. Three men are chosen to eat the babe, and when all is eaten, they begin to dance. After a while the central figure shakes his leg violently and from the thigh the child appears."

The idea that the soul of man or woman has the power to leave its human form and enter into that of its "affinity" is firmly held by these people. In proof of this the author relates the story of a Yoruba steward, who was caught by a crocodile one evening and dragged below into the river. After investigation it was found that the crocodile was supposed to contain the soul of a Juju man who, when angered against the Government, wreaked his vengeance on the officials. On this particular evening he was especially incensed against an official who had reported his evil deeds, and waited until he could have his revenge.

There are, according to Mr. Amaury Talbot, three secret societies of the Ibibio, the Egbo, Idiong, and Isong. Their initiatory ceremonies bear a strong resemblance to Freemasonry, and any non-member attending the ceremony would be punished severely. In an interesting chapter entitled social organisation and tabu, the author lays stress on the fact that slaves taken in war were most kindly treated, and in many cases allowed to marry into their masters' family. Amongst the food taboos the animals forbidden were snakes, monkeys, and lizards. In this chapter Mr. Amaury Talbot relates an experience he had whilst District Commissioner. Three of the head chiefs

of Ikotobo came to him one morning trembling with fear, and asked him if it were true that he was going to use tonite for the removal of some tree-trunks which were blocking a certain creek. Mr. Amaury Talbot assured them that no orders had been given to that effect, and demanded the cause of their fear. The answer was as follows: "Deep down in the waters of the creek are tiny houses such as ants make. Near these houses live fishes, with skins as black as our own. In these fishes are the souls of our ancestors, and for every fish you would kill one of our people would die."

Space does not allow one to quote the telling descriptions of bush fires, wide expanses of beautiful scenery, or vast pools of water given in this book. With regard to fire-worship, which still goes on, the author says: "In lands where such demonstrations of the power of fire are matters of constant occurrence, it is not to be wondered at that many rites of fire-worship should here still form part of the race. On a certain day in the wet season some towns, for instance, make two great bonfires, one on each side of the road. Then they gather their cattle, sheep, and goats into a herd and drive them between the walls of flame. This ceremony is said to destroy evil influences which might otherwise have caused sickness to fall upon the beasts during the year, and is also considered to act as a fecundative agent."

Upon realising the spirit in which the author has written this book, one is not surprised to find within its pages a graceful note of appreciation to two most valuable helpers. One is Mr. W. W. Eakin, of the Kwa Ibo Mission, and the other Etubom Nyung Ansa, better known by his English name, Chief Daniel Henshaw, Native Political Agent for the district. "He is," writes the author, "a Chief of pure blood and head of one of the seven ruling families of Calabar, where his ancestors were found in possession on the coming of the early traders."

Although Mr. Amaury Talbot fully realises the vast amount of work still to be accomplished in this part of West Africa, he is not discouraged; for he has an interesting theory regarding the solution of the problems before the administrators. "The darker aspects of many rites and beliefs may be attributed," he says, "in great part at least, to the shadow cast over the minds of the people by that dense tropical forest which covers such vast stretches of the West Coast, or by the mangrove swamps which surround low-lying lands. In open sun-lit country, like the wide plains of Northern Nigeria and the Sudan, the more revolting customs seem to be dying out, as was the case in Egypt with the cutting of the bush, and in Europe with the thinning of the great forests."

Climatology, Objective and Subjective.

(1) *Die Klimate der Erde: Grundriss der Klimakunde.* Von Prof. Dr. W. Köppen. Pp. x+369+8 Tafeln. (Berlin und Leipzig: Walter de Gruyter und Co., 1923.) 7*s.* 2*d.*

(2) *Die geopsychischen Erscheinungen: Wetter und Klima, Boden und Landschaft in ihrem Einfluss auf das Seelenleben.* Dargestellt von Prof. Dr. Willy Hellpach. Dritte, neubearbeitete Auflage. Pp. xx+531. (Leipzig: Wilhelm Engelmann, 1923.) 14*s.*

DEEPLY rooted in the human mind is the instinct to collect "specimens," to classify them and to arrange them in museums. Prof. Köppen is the exponent of this instinct in the domain of climatology; his specimens are data of temperature and rainfall. Some years ago he laid down his system of classification, and now he has completed and arranged his collection. "The Climates of the Earth" (1) is a handbook and guide to the Museum of Climatology. After a general introduction dealing along the usual lines with the objects and methods of the study of climate and the factors which govern the distribution of the climatic elements, we have a full account of the system of classification and notation, followed by generalised and then by more local descriptions of the different types. Finally there are sixty-nine pages of "specimens," namely, the mean and extreme temperatures, the rainfall, and in some cases the cloudiness and humidity for more than a thousand stations.

The results of such a systematic treatment are not difficult to foresee. There is an orderly development of the subject-matter which effects great economy of space. The ordinary political boundaries are ignored; Asia, for example, is treated under four headings, the tropical rain-belt, the dry region, the warm temperate rain area, and the boreal zone. The description is logically complete, and yet occupies only twenty-one pages. There is an even greater triumph of system in the frontispiece map, from which, knowing the notation, it is possible to read off the salient features of the climate of any part of the world with great ease and definiteness. On the other hand, when everything is subordinated to a system, there is no room for details which from the author's point of view are irrelevant. Climatic peculiarities which the visitor might regard as of some importance, such as the mistral of the Mediterranean, are either ignored or dismissed in a brief and colourless sentence. The use of the shorthand notation accentuates this impression of flatness; the statement that the climate of a large region is *Cfb* is no doubt complete and accurate, but until the interpretation becomes automatic, it is irritating

rather than inspiring, especially to the non-German reader who has to deal with contractions in a language not his own.

To sum up, the book gives a clear insight into the causes underlying the distribution of the main climatic features over the globe, and for this reason should be of great value to teachers, who can make use of the excellent arrangement of the material while filling in the details from other sources. The statistician will welcome it for the amount of information it conveys in a small space, but the ordinary reader will find it rather devoid of human interest and picturesque illustration. The author certainly has the courage of his convictions, for while there is a very complete index to the tables, except for the table of contents at the beginning there is no index to the text.

(2) "Geopsychical Phenomena" is a book of a very different stamp. The author is a nerve specialist, whose interest lies in the reaction of man to his natural environment, and from his medical experience he is able to write with great authority on the mechanism of these reactions. For him the basis of a classification of climates is not the mean temperature and rainfall, but the influence on human well-being, especially as exerted through the mind, either by means of the senses or by the general level of health induced. Climates (and also temporary weather conditions) are classed as enervating or bracing, and the instrument of research is not the thermometer or rain-gauge but the "weather man," who experiences these effects to the greatest degree. Thus the book is almost entirely subjective; it is of great human interest, as is proved by its having reached a third edition.

The chief sources of this interest are the vigorous detail and the fact that most of us have experienced in a greater or less degree the feelings described, for example, as accompanying the passage of a thunderstorm. But there is often a lack of definiteness, partly due to the subject-matter, which does not lend itself to exact treatment, and partly because the weather elements which the author regards as most important are not always those about which climatologists have most to tell us. Atmospheric electricity is credited with great effects, while the powers of solar radiation of various wave-lengths are well known, but more data about the distribution of these elements are required before the subject can be treated definitely. Hence the author is not entirely unjustified in blaming meteorologists for a certain inconclusiveness in some of his remarks. An experiment of even greater difficulty and, if possible, of even greater interest, is the attempt to measure the effects of that branch of the environment termed the landscape. The analysis mainly consists of a study of colour and form, and is certainly justified by its importance, but at the present stage a definite measure of the health-value of a landscape is scarcely to be expected.

It is interesting to note that even in such a subject as the "feel" of weather, numerical methods have obtained a foothold. Thus several formulæ are quoted which express the sultriness of the air numerically in terms of the temperature and humidity. None of them is quite successful, but they constitute a beginning. The author does not appear to be acquainted with recent British work on this and allied subjects, owing to difficulty in obtaining the necessary journals.

The book should be of great value to doctors, of interest to meteorologists and geographers, and it has also a strong appeal to the general reader, but only those who read German readily should attempt it. Once again we have to bewail the absence of an alphabetical index, and this time the omission is more serious.

The Teaching of Mathematics in France.

(1) *Cours complet de mathématiques spéciales.* Par Prof. J. Haag. Tome 3: Mécanique. Pp. viii + 190. (Paris: Gauthier-Villars et Cie, 1922.) 12 francs.

(2) *La Composition de mathématiques dans l'examen d'admission à l'École Polytechnique de* 1901 *à* 1921 Par F. Michel et M. Potron. Pp. xii + 452. (Paris: Gauthier-Villars et Cie, 1922.) 40 francs.

(3) *Dynamique des solides.* Par Dr. J. Reveille. (Encyclopédie de Mécanique appliquée.) Pp. 506 (Paris: J.-B. Baillière et fils, 1923.) 40 francs.

MATHEMATICAL teaching in Great Britain, at least in its more elementary stages, makes its appeal to the intuitive faculties of the pupil, and the mathematical and mechanical principles and methods are made as real and immediate as possible. If Prof. Haag's treatises are representative samples of French mathematical text-books, then they indicate that French mathematical teaching aims more at capturing the imagination of the learner and exercising his reasoning faculties in abstract terms. The professor's aim is to provide books for candidates who wish to enter the famous École Polytechnique and the École Normale Supérieure in Paris, and thus the book caters for the better class of pupils from the lycées or secondary schools. The atmosphere of the present book (1), with its emphasis on mechanical principles, is nevertheless highly abstract and theoretical. The treatment is interesting and possesses the elegance we expect from French writers. The author claims that "Un livre de mathématiques ne doit pas se lire comme un roman; plus il exige de travail et de

réflexion plus il est profitable." An English schoolboy would almost certainly read such a book like a novel, especially as in this "Cours" the examples are relegated to separate volumes. The author emphasises the importance of the examples and insists that the student should do a considerable number himself. French pupils can no doubt use such books: the English pupil needs something more concrete—but it would do any English student a considerable amount of good to read Prof. Haag's volume on mechanics, and study his interesting account of the principles of the subject.

This abstract and theoretical character is also to be found in the collection of mathematical questions set at the entrance examinations to the École Polytechnique, and issued with solutions by MM. Michel and Potron (2). The subjects included are algebra with analysis (*i.e.* calculus), trigonometry, geometry, and mechanics. Numerical examples are very rare, being limited apparently to the actual solution of equations. Even the questions on mechanics are very abstract and bear little relation to life, but they seem to test very well the fundamental principles. In each question the examiners suggest a topic or a mode of treatment, with a number of applications: the candidate's duty is to apply his knowledge to the series of questions on this one topic or method. We quote as an illustration *one* "composition" under the caption: Analytical Geometry and Mechanics.

I. On the logarithmic spiral $r = ae^{m\theta}$ take M_0, M defined by θ_0, θ.

(1) Find the centre of gravity G of the arc M_0M.
(2) Find the limiting position of G as M_0 tends towards the pole O.

II. When M_0 is at O, let the polar angle θ of M increase at the rate of 1 radian per second.

(1) Investigate the curve Γ which is the locus of G.
(2) Find completely the velocity V and acceleration A of G for any value of θ.

III. Instead of the spiral consider any curve C. The end of the arc $M_0M(=l)$ of this curve is supposed to move along C according to some given law in terms of the time. Given the centre of gravity G of the arc M_0M, the end M of the arc, the tangent MT at M, the length l of M_0M, the first two differential coefficients (l', l'') of l with respect to the time, find completely

(1) The velocity V of G.
(2) The acceleration A of G.

IV. In the particular case when the curve C consists of two rectilinear segments M_0O, OM

(1) Find the centre of gravity G of M_0M.
(2) Find the locus Γ of G as the segment OM assumes all possible positions round O as a pivot in the given plane.

This should be sufficient to indicate the style of the questions. The solutions are interesting and occasionally elegant.

(3) Dr. Reveille's book is a compromise between the abstract and the practical, as befits a volume forming part of the "Encyclopédie de Mécanique appliquée" issued under the direction of Prof. Lecornu. It combines in a really competent manner the theoretical and the industrial aspects of the subject of rigid dynamics. There is a good account of the motion of a body about a fixed axis, of general two-dimensional rigid dynamics, of the motion of a rigid body about a fixed point including both the Poinsot construction and the elliptic function solution, of the top, of a rigid body on a plane, and of the theory of gyroscopic motion. The whole forms a very good account of the most useful and important parts of rigid dynamics, including the method of Lagrange's Equations applied to holonomic and non-holonomic systems. At the same time the author discusses in considerable detail a large number of practical applications, such as the motion of millstones, the treadmill, the hoop, the bicycle, including looping the loop, and all kinds of gyroscopic methods, such as Foucault's experiment, Brennan's monorail, the motion of torpedoes, and various forms of gyroscopic compasses.

S. BRODETSKY.

Ambroise Paré.

Selections from the Works of Ambroise Paré. With Short Biography and Explanatory and Bibliographical Notes, by Dorothea Waley Singer. (Medical Classics Series.) Pp. iv+246. (London: J. Bale, Sons and Danielsson, Ltd., 1924.) 12*s.* 6*d.* net.

AMBROISE PARÉ (1510 ?–1590), although brought up as a barber surgeon, lived to become the founder of French surgery, one of its shining lights, and one of the greatest military surgeons of all time. He published a great deal during his lifetime, and his collected works appeared in many editions after his death. There must have been a very large number of copies of his works, and yet the earlier ones are excessively rare or even unobtainable in some of the largest medical libraries. Paré's experiences were bought practically in numerous campaigns, battles, and sieges in which he served various French kings against that stormy petrel of the sixteenth century, Charles V. Apart from his practical skill as a surgeon, Paré's name has been honoured in all subsequent ages as the ideal of an honest, modest man of a most humane disposition,

with an intense feeling of sympathy for the wounded soldier gashed by gunshot wounds or arrow-heads. His modesty is summed up in his motto, "Je le pansay et Dieu le guarit."

After the exhaustive work of Malgaigne and the charming work of Stephen Paget it is difficult to give a new view of Paré which is equal to theirs. Mrs. Singer set herself a difficult task, and in our judgment she has not been altogether successful. Her book consists of an introduction of 46 pages, in which the main facts of Paré's life and work are set out, while the rest of the book is a reprint of the English translation which Thomas Johnson made in 1634 from the Latin translation of Paré's "Œuvres" in 1582, by Paré's pupil Jacques Guillemeau. A comparison of the original French with Johnson's translation shows that Paré lost somewhat in his English garb, and it would probably have been better to replace the archaic Johnsonian phraseology by a modern English translation of the sections quoted.

A work like that which Mrs. Singer has attempted really requires co-operative editing in the present state of knowledge. A typical example may suffice. With reference to a case, described and cured by Paré, of a certain Guordon, Seigneur d'Achindon, Mrs. Singer gives a footnote (p. 68) which is almost certainly incorrect. She has been unable, she says, to trace Achindon, but there is no difficulty about this, as Auchindoun was the stronghold of the Huntly family, and still exists as a well-known ruin near Dufftown, N.B. The Guordon of Paré was almost certainly not the person suggested in Mrs. Singer's footnote, but Sir Adam Gordon of Auchindoun—the "Edom of Gordon" of Scottish ballad fame. This gay Gordon, after various adventures at Corrichie and elsewhere, burned the lady of Towie in her castle in 1574 and fled to France, where he was pursued by one of her kinsmen, Arthur Forbes. A most circumstantial account of Forbes's attempt to assassinate Auchindoun will be found in Robert Gordon's "History of the Earldom of Sutherland," 1830, p. 170, and this agrees exactly with the account of the Seigneur d'Achindon of Ambroise Paré. The matter we have referred to is perhaps trivial, but in works on medical history it is well to be accurate.

Our Bookshelf.

The Moon-Element: an Introduction to the Wonders of Selenium. By Dr. E. E. Fournier d'Albe. Pp. 166+8 plates. (London: T. Fisher Unwin, Ltd., 1924.) 10*s.* 6*d.* net.

DR. FOURNIER D'ALBE'S book is chiefly a history of the optophone, the instrument for enabling the blind to read ordinary print. This history claims about one-third of the volume and deals in chronological order with the development of the device from its invention by Dr. Fournier in 1913 to its present form in which Messrs. Barr and Stroud, and, in particular, Dr. Archibald Barr of that firm, have collaborated. The long eighth chapter is a record of the pertinacity of the author for many years in the face of discouragement and opposition, and is almost a biography. Indeed, a not unsuitable title for the chapter, if not for the whole book, might be "The Triumph of the Optophone." It is natural enough that an author should write at length on the fruit of his own efforts. Here, in so small a volume, the effect has been to curtail too much what could have been written about other important applications of selenium. The optophone is the only instrument described in anything like detail. Most of the other selenium devices are referred to only briefly, and a few get no mention at all.

Dr. Fournier is not afraid to speculate; he does so whole-heartedly in more than one place. In the first chapter entitled "Electricity and Light," he gives himself especially free rein when he pictures "the two kinds of electricity as consisting of living beings of sub-atomic dimensions, divided, like the higher animalcules, into two sexes, and living their life on a scale of time and space removed a millionfold from the latter." The inclusion of this first chapter, much of which bears little relation to the scientific treatment of the subject in hand, definitely marks the book as popular rather than technical. Perhaps, indeed, this has been the purpose of the author, although it is not so defined in the preface. His enthusiasm for his subject sometimes displaces the impartiality proper to scientific description, and he would probably be prepared now to admit that his hypothetical and comprehensive condemnation of all selenium cells, save those of his own construction, as expressed in line 24, page 70, is scarcely worthy of an investigator of his own attainments.

In spite of its scientific defects the book is most eminently readable. Dr. Fournier's wide experience as an author in varied fields is a guarantee of that. He has a way with him in writing that grips the reader; the reviewer himself read the book from cover to cover in a single sitting. Dr. Fournier writes with the authority of a recognised expert, and if, as the title rather suggests, he has aimed at arousing the spirit of wondering interest among the general public, he will without doubt succeed. A. O. R.

Pulpwood and Wood Pulp in North America. By R. S. Kellogg. Pp. xii+273. (London: McGraw-Hill Publishing Co., Ltd., 1923.) 20*s.*

THE manufacture of paper from wood pulp began on a commercial scale in 1854, as before that date the raw material ordinarily used was cotton and linen rags, esparto grass, straw, and hemp. The first process of making paper from timber was a purely mechanical one, by which the fibres of the wood, after being torn apart by grindstones under a stream of water, were transformed into so-called "mechanical" pulp, which is still the source of the cheaper kinds of paper. Tilghman in 1867 discovered the disintegrating action of sulphurous acid upon wood; and this formed the basis of the invention of the sulphite process, which was started commercially in Sweden

in 1874. The resulting product, "chemical" wood pulp, is used for the better classes of paper.

The wood pulp industry in a little more than half a century has grown to an enormous extent in Scandinavia, Germany, and North America. This is not to be wondered at, as the consumption of paper is increasing all over the world by leaps and bounds. In 1922 the paper used in the United States for newspapers alone amounted to 45 lb. per head of the population.

Mr. Kellogg gives a detailed account of the pulp industry as it is now carried on in Canada and in the United States. He describes the various processes of manufacture and the different species of woods employed, and gives statistics and charts of costs and production. He deals very fully with the important question of the timber supply now available in North America; and discusses the annual drain on the forests, due to felling for all purposes and loss by fire, insects, and disease. It is estimated that the timber in the United States at the present rate of consumption will last only for sixty-four years. The need for scientific forestry and better modes of protection is urgent in the extreme. The book is well illustrated with diagrams, maps, and reproductions of photographs, which depict forest scenes, pulp mills, and machinery. The view of a nursery in Canada, where five million seedling trees are raised annually, shows that some of the great lumber companies are at last taking active measures to replenish the areas that have been devastated by reckless felling and disastrous fires.

An Introduction to the Theory of Optics. By Sir Arthur Schuster. Third edition, revised and enlarged by the Author and Prof. John William Nicholson. Pp. xv+397. (London: E. Arnold and Co., 1924.) 18*s*. net.

THERE is no need to set out here the merits of Sir Arthur Schuster's book on optics, and in describing the new edition, in which he has had the collaboration of Dr. J. W. Nicholson, we may confine ourselves to the novelties that have been introduced. These include descriptions of some of the newer optical instruments and processes, among them an excellent account of Michelson's method of measuring stellar diameters.

The main addition is in two chapters at the end, which deal with the quantum theory. In the first of them there is a good account of Bohr's theory of the hydrogen spectrum, which is followed by a short discussion of Planck's law of radiation. In this there is an unfortunate misprint, giving preference to Planck's second hypothesis over his first, instead of the other way about. We may also regret the absence of any mention of the thermodynamic principles which should serve as the basis of any discussion of radiation; indeed a detailed discussion of "black body radiation" would be a proper complement to the excellent descriptions of white light that are found earlier in the book. The account of the partition law is adequate, though we may confess a doubt whether a student coming fresh to the subject would find it convincing. However, this objection applies to nearly all presentations of the subject which approach it without a thorough consideration of statistical principles.

The last chapter deals with the dynamical theory of spectra. It follows mainly the work of Sommerfeld and his school, giving the three dimensional quantisation, fine structure, etc., and then Sommerfeld's construction of the formulæ of Rydberg and Ritz. It also contains an account of ionisation potentials and concludes with the dynamical theory of the separation of variables, the principle of adiabatic invariance and the correspondence principle which is applied to the Stark effect. Altogether the whole constitutes a good outline of many of the more recent optical applications of the quantum theory.

James Dewar, 1842–1923: a Friday Evening Lecture to the Members of the Royal Institution, on January 18, 1924. By Henry E. Armstrong. Pp. 32. (London: Ernest Benn, Ltd., 1924.) 1*s*. 6*d*. net.

EULOGY, whether spoken or written, makes greater demands upon judgment, knowledge, and taste than any literary task—so difficult is it, while maintaining equipoise between the elements that compose virility and virtue, to avoid transgression into adulation too fervid or into praise too faint. When eulogy relates, however, to a friend who has passed beyond mortal life, the task is to some writers made easier, for thoughts then spring from the depths in proverbial abundance, and there is more of reverence to steady the balance. It is in these circumstances that Prof. Armstrong pays tribute to his friend James Dewar. He extols the great philosopher in terms the substance of which is already familiar to those who early in the year followed the proceedings of the Royal Institution; but it is well that the discourse then so finely wrought in the rough, and now polished, and set in the gold of generous appreciation, should take this permanent form. Here and there some comparisons may be too vivid, here and there the detail may be weak, and the allusions may occasionally be inconsequent and in excess, but the work as a whole reveals with truth and justice the skill, genius, character, and nobility of purpose of James Dewar, in a manner to encourage and to inspire all who study it in a mood to respond. R. A.

Assyrian Medical Texts: from the Originals in the British Museum. By R. Campbell Thompson. Pp. vii+107. (London: Oxford University Press, 1923.) 42*s*. net.

IN our issue of April 12, p. 529, we published a note on a reprint from the Proceedings of the Royal Society of Medicine by the same author on the same subject. The present work is a series of 107 plates containing the text of 660 cuneiform medical tablets for the most part previously unpublished. They are from the Royal Library of Ashurbanipal, now preserved in the British Museum, and date from the seventh century B.C. It is perhaps to be regretted that the preface is not given in greater detail, as otherwise the work is intelligible only to Assyriologists.

Bell's Card of Logarithms and Science Tables. 10 in. × 8½ in. (London: G. Bell and Sons, Ltd., 1924.) 2*s*. net per dozen.

THIS is a single card of convenient size for use in classrooms, giving four figure logarithms, trigonometrical tables for intervals of one degree, and a number of useful physical and chemical constants.

Liquid Crystals—Soap Solutions and X-rays.

AMONGST the earliest examples of Lehmann's liquid crystals were the transparent double cones of ammonium oleate. MacLennan's work has shown that this transparent anisotropic state is common in soap solutions. The accompanying photograph (Fig. 1), taken by Mr. W. J. Elford in this laboratory at the suggestion of my colleague Mr. Piper and myself, shows the very striking appearance presented by these transparent solutions when examined in slightly convergent light between crossed Nicols. The transparent conic anisotropic liquid shown occurs in 2·5 weight normal potassium laurate at 45° C., magnification 200 diameters, and it exhibits very clearly the characteristic fan-like structure composed of focal lines.

A glance at the photograph shows the aptness of

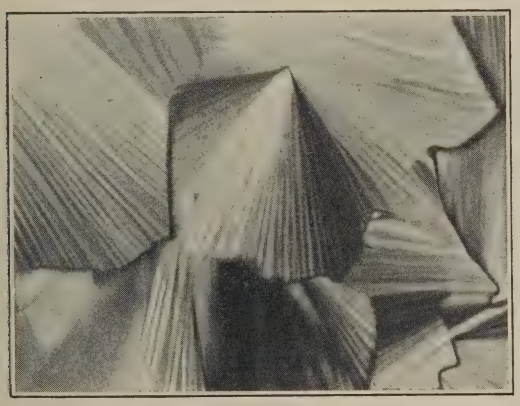

FIG. 1.—2.5 N potassium laurate. Transparent anisotropic plastic phase (40-50° C.). × 200 diameters.

Friedel's designation of this state of matter, namely, "liquide à conique," which he now proposes to supersede by the term smegmatic (smectique) in order to place soap curds in this class. We have found, however, that every aqueous soap such as potassium laurate may be prepared in each of the forms: hexagonal crystals, curd fibres, and anisotropic and isotropic liquids.

Piper and Grindley found a year ago that the curd fibres show an X-ray structure resembling Müller and Shearer's X-ray diagrams for crystals of fatty acid, whereas anisotropic liquids have given negative results. Following Friedel, they ascribed these curds to the "smegmatic condition." Friedel nevertheless expressly states that for any substance there can be only one "smegmatic" form, and that there are no discontinuities in a "smegmatic" specimen other than the apparent focal lines. Now curd fibres are discrete, and they differ greatly in almost every way from the conic anisotropic liquid soap illustrated in the accompanying photograph, which is seen to typify Friedel's "état smectique" or "liquide à conique." It is therefore evident that Friedel's attempt to classify opaque soap curds as "smegmatic" when that state is already filled by the transparent conic liquid soaps would disrupt his classification of liquid crystals and necessitate the *ad hoc* setting up of a new group within which to include such curds.

Earth Tides and Ocean Tides.

I AM in entire sympathy with Mr. Lambert's plea in NATURE of June 21, p. 889, for further research on earth tides. It is much to be regretted that so little has hitherto been effected in that direction. I only wish our "far-flung" Empire had done its share in investigating geophysical problems connected with the earth's crust. I fancy, however, that the horizontal pendulum would be more easily and cheaply installed in outlying stations than the interferometer apparatus of Michelson and Gale. The Milne-Shaw seismometer can be adapted for the purpose by the addition of a stationary mirror tracing a reference line on the record.

Mr. Lambert refers to the "greater apparent rigidity in the prime vertical than in the meridian . . . in various places near the Baltic Sea." This presumably applies to the horizontal pendulum observations at Potsdam and Dorpat (in Esthonia). He goes on to say that "when various ingenious explanations of this peculiarity were found to be untenable, it came finally to be accepted that the true explanation lay in the effect of the oceanic tides."

At Potsdam, where the inequality of the rigidity in different directions is much greater than at Dorpat, the direction of maximum rigidity is apparently not due east and west but about 8° north of west and south of east. This is approximately parallel to the strike of the later foldings in the older rocks to the south and no doubt also of those covered by the Quaternary deposits in the neighbourhood of Potsdam itself. This folding probably extends some miles down in the earth's crust and must diminish the rigidity in a direction at right angles to its strike. I fail to see why this explanation is untenable.

It would be interesting to ascertain how rigidity varies with direction in the neighbourhood of lines of north and south folding.

The Structure of Molecules in relation to their Optical Anisotropy.

As is well known, the light scattered transversely when traversing a column of gas or vapour is not completely polarised, the defect of polarisation depending on the nature of the substance. The explanation of this phenomenon as developed by the late Lord Rayleigh, Born, Sir J. J. Thomson and others is that the molecules which scatter the light are optically anisotropic, that is, have different refractivities in different directions, and are oriented arbitrarily in space. From the point of view of dispersion-theory, the interpretation usually given is that the electrons responsible for the refraction of light are anisotropically bound in the molecule.

This way of regarding the matter, though perhaps not formally incorrect, does not hold out much hope of progress in interpreting the experimental results, owing to the scantiness of our knowledge regarding the manner in which the dispersion-electrons are bound in complex molecules. Recently, under the writer's direction, a series of accurate measurements have been made in his laboratory of the scattering of light in some thirty different gases and vapours by Mr. A. S. Ganesan, and in more than sixty different transparent liquids (chiefly organic compounds) by Mr. S. Krishnan, and the empirical knowledge thus accumulated of the relation between light-scattering and chemical constitution emphasised the unsatisfactoriness of the position of the subject on the theoretical side. Thus,

for example, the observations showed that molecules containing elongated chains of CH_2 groups and therefore highly unsymmetrical in shape are, optically, much more nearly *isotropic* than benzene, toluene and other compounds of the aromatic series.

These and other results stand in need of explanation, and it is the purpose of this note briefly to indicate a method of dealing with the matter which is at least a useful working hypothesis. The suggestion is that the optical anisotropy of the molecule is due, in the main, to the mutual influence of the electric doublets induced by the external field in its constituent atoms, the latter, individually, being themselves more or less completely isotropic. A similar idea has recently been used very successfully by W. L. Bragg to explain the doubly-refractive character of substances in the solid crystalline state, *e.g.* calcite and aragonite.

Following up the working hypothesis indicated, Dr. K. R. Ramanathan has, at the suggestion of the writer, calculated the degree of optical anisotropy to be expected theoretically for the molecules of a number of substances in the gaseous state and obtained most encouraging results. The fullest test of the theory will be that furnished by the series of organic vapours studied; the detailed calculations necessary for this purpose have been undertaken. Qualitatively, it is not difficult to see that the closer packing of the atoms in the benzene rings compared with that in the chain compounds would enhance their mutual influence, and that, consequently, the greater anisotropy exhibited by the compounds of the aromatic series is what we should expect on the hypothesis suggested. Emission of Volcanic Gases.

I TOO have been shown the effect described by Prof. Conway in NATURE of June 21, p. 891, at the Solfatara, near Naples. I was inclined to believe in its objective reality, but was not sure. I write to suggest that some scientific man who is taking his holiday in that neighbourhood should carry a camera with him, and obtain a photograph before, and another after, the torch has been applied to the vent. In that way I think it would be easy to decide objectively whether the distant vents are affected or not. RAYLEIGH.

69 Cadogan Square, S.W.1, June 21.

I WAS glad to see Prof. Conway's letter on the "Emission of Volcanic Gases" in NATURE of June 21, in which he directs attention to the remarkable phenomenon observed at the volcano of Solfatara when a lighted torch is waved over one of the vent-holes in the crater.

I was also present at Naples on the occasion mentioned, and, along with some friends, took the opportunity of visiting Solfatara, where we observed the phenomenon described by Prof. Conway.

The increase in the amount of fumes emitted was quite unmistakable. A. A. ROBB.

Cambridge, June 22.

I HAVE seen repeatedly during the last thirty-eight years the evocation of gas at Solfatara, described by Prof. Conway in NATURE of June 21, p. 891. The phenomenon is certainly not subjective, neither is it trickery. I venture to offer the hypothesis that, under the floor of the crater, deep caverns are filled with volcanic gases, the equilibrium of which is unstable to a small change in atmospheric pressure, such a change being effected when the air above a group of crevices is heated by the torch. The crevices must be connected with the deep reservoir by passages, and the gas must be generated into the reservoir at a pressure exceeding atmospheric pressure by the pressure due to the vertical column of heavy gas in the passages, added to the pressure necessary to produce the flow of the gas through their length.

Instability is due to the fact that gas drawn up to the torch is hot gas, which therefore rarefies the air more, and so draws up more and hotter gas; and further, that the torch drawing gas from the passages to the crevice must draw also gas from the deep reservoir to the passages and from the lower part of the passages to their upper part. In all cases the gas passes from deeper and therefore hotter strata to higher and therefore cooler strata—so that the whole gaseous column becomes warmer and therefore lighter than it was before. Consequently the weight of the column no longer equipoises the pressure in the deep reservoir, and this therefore forces out gas by the passages through every aperture, the uprush further heating and lightening the column, and therefore renewing itself, until a second equilibrium is reached at a lower reservoir pressure plus a more rapid upward flow of gas. Eventual slackening of this flow and reversal of the steps must be brought about by the cooling of the deep chambers producing a lower pressure of generation; this reduces the rate of flow and therefore increases the time which is passed by the column in the cooler strata. The column therefore becomes cooler and heavier and requires higher pressure in the reservoir to lift it, while the escaping gas is cooler and the rarefaction of the external air lessens. Each consequence reinforces its cause, until the *status quo ante* is reached with the external atmosphere at its original temperature and pressure.

Evidence for the existence of large unstable gaseous reservoirs has lately appeared to me to concern not only the colliery engineer, but also the biologist. It seems possible that some of H. Munro Fox's interesting lunar cycles in life-histories, especially of marine organisms,[1] might conceivably be explained by the earth-wave of spring-tides distorting the walls of subterranean caverns filled with gas, and so releasing an importantly greater quantity of carbon dioxide, etc., at the new and full moon. Thus the constitution of the sea-water in their neighbourhood would have a fortnightly and monthly chemical periodicity which would produce a physiological periodicity in inhabitants sensitive to those constituents.

GEO. P. BIDDER.

Cambridge, June 22.

PROF. CONWAY'S letter in NATURE of June 21 again directs attention to this remarkable phenomenon. Since my former visit, my daughter, Ruth Place, has visited the volcano for further investigation, and we suggest that the sudden emanation of visible gases and vapours may be the effect of ionisation started by the torch flame.

There may be another explanation. The whole system must be charged with superheated aqueous vapour, the temperature varying from 99° C. to 161° C., as observed by Prof. Mercalli, the lower temperature obviously that taken near the surface. When the organic substance, namely, resin torch, or even a bunch of brushwood, paper, etc., is burnt, it will produce water which will condense the hot aqueous vapour and form fog, and so will quickly influence the whole zone and become visible over an extensive range of ground. JOHN PLACE.

16 The Avenue, Beckenham, Kent.
June 30.

[1] At Naples *Nereis dumerilii* and *Dictyota dichotoma*, both breeding fortnightly (Proc. Roy. Soc., vol. 95, p. 544).—Note that there are effervescent hot springs known to bathers in the sea at Bagnoli, near the Solfatara.

Explanation of Abnormal Low Voltage Arcs.

IT is well established that arcs in gases or vapours may be maintained at voltages as low as their ionising potentials, or, in cases where cumulative ionisation is possible, as low as their radiating potentials, provided a hot cathode is used as a source of electrons to stimulate the arc. Considerable discussion has arisen over certain cases in which arcs have been maintained at still lower voltages,[1] since at such voltages the electrons are known not to effect partial or complete ionisation of molecules with which they collide.

Recently Bar, v. Laue and Meyer [2] and, independently, the present writers,[3] have shown that this may be accounted for by the existence of oscillations the peak voltage of which always exceeds the lowest radiating potential of the gas. An experimental and theoretical study of these oscillations has shown them to be in the nature of current interruptions occasioned by the rise in current and consequent drop in voltage occurring when the ionisation is sufficient to create a positive space charge around the filament. Under such conditions there is nothing to prevent a rise in current to its saturation value. With such a rise, the increased potential drop in the series resistance reduces the voltage across the arc. If this reduction takes the voltage to a value below the lowest critical potential of the gas, the current can be maintained only so long as the supply of previously excited atoms persists, after which the current decreases, the voltage rises, and the cycle is repeated. Reactance in the circuit is not, as believed by Bar, v. Laue and Meyer, essential to the oscillations, though it does affect the wave form.

The above phenomenon does not explain all cases of abnormal low voltage arcs, however, for we have maintained arcs in helium, mercury vapour and argon, without oscillations, at voltages well below the lowest critical voltages of the gases. Also Holst and Osterhuis [4] have reported steady arcs in argon at 3·5 volts and neon at 7·5 volts, whereas the lowest critical potentials of these gases are 11·5 and 16·7 volts respectively. To account for this, these authors have proposed a rather elaborate theory of progressive ionisation. The following experiments, however, explain entirely these abnormally low voltages simply on the basis of well-known phenomena.

A short hot-filament cathode and a sheet nickel anode were placed about 1 cm. apart, and a 3 mm. length of 1 mil wire projecting from a glass stem was introduced as an exploring electrode in a bulb filled with pure argon at 2 mm. pressure. This electrode was used according to Langmuir's recent method,[5] and was movable to different points in the discharge by a flexible copper-to-glass seal.

It was found that the arc could easily be maintained at an applied voltage of about 4 volts, without oscillations. Under these conditions, however, *the gas near the filament was found to be at a potential of about 11·5 volts above that of the filament*, and there was an electric field in the direction reverse to the applied field throughout most of the space between the electrodes. Furthermore, the concentration of ions, either positive or negative, was found to decrease from about 100×10^{10} per cc. near the cathode to about 2×10^{10} per cc. near the anode. The average kinetic energy of the electrons outside the region of the cathode drop was found to vary from 2 to 4, in equivalent volts. Analogous results were found in a mercury arc, operating at about 3·5 volts.

Evidently there is *always* a sufficient cathode drop to produce ionisation. If the ionisation is intense, positive as well as negative ions move toward the anode, and at approximately equal rates. To cause this, the reverse electric field, caused by difference in rates of diffusion of electrons and positive ions, takes such a value as to cause the two types of ions to move toward the anode at nearly equal rates. It is easily shown that the number of ions of either sign is at least a million times greater than the excess of one kind over the other, except in the region of the cathode drop.

A fuller treatment of this problem and its significance in the Geissler tube discharge will soon be published.

We are indebted to Dr. Irving Langmuir for suggesting this general line of explanation of the abnormal arc.

De Broglie's Theory of the Quantum and the Doppler Principle.

L. DE BROGLIE (*Phil. Mag.*, Feb. 1924) has recently suggested a theory of the quantum in which the quantum is supposed to be a corpuscle of exceedingly small rest mass M which moves with a velocity βc, where β is less than unity by an exceedingly small amount. The momentum of such a corpuscle is $M\beta c/\sqrt{1-\beta^2}$, and is equal to that of the light quantum $h\nu/c$. Since β is so nearly unity, the momentum may be written as $Mc/\sqrt{1-\beta^2}$. Different values of the frequency ν are explained as being due to different values of β.

Let us suppose that an atom is moving towards the observer with a velocity $\beta_1 c$, and that while moving with this velocity the atom ejects a quantum in the direction of the observer, the frequency of the quantum being ν_0 and its velocity $\beta_0 c$ relative to an observer on the atom. The momentum of the quantum relative to the atom is then $h\nu_0/c = Mc/\sqrt{1-\beta_0^2}$. By applying the relativity theorem of the addition of velocities, we have that, if βc is the velocity of the quantum corpuscle relative to the stationary observer,

$$\beta c = (\beta_0 + \beta_1)c/(1 + \beta_0\beta_1).$$

Hence
$$1 - \beta^2 = \frac{(1-\beta_0^2)(1-\beta_1^2)}{(1+\beta_0\beta_1)^2}.$$

Remembering that β_0 very nearly equals unity, and assuming that β_1 is small, we have

$$1 - \beta^2 = (1-\beta_0^2)(1-\beta_1)^2.$$

Hence if ν is the frequency relative to the stationary observer we have

$$h\nu/c = Mc/\sqrt{1-\beta^2} = Mc/(1-\beta_1)\sqrt{1-\beta_0^2} = h\nu_0/c(1-\beta_1).$$

If now we put $\beta_1 = v/c$, where v is the velocity of the atom relative to the stationary observer, we have

$$\nu = \nu_0 c/(c-v),$$

which is the equation expressing the Doppler principle when the velocity v of the radiating atom is small compared with c.

G. E. M. JAUNCEY.
Washington University,
St. Louis, Mo., May 23.

THE result obtained by Mr. Jauncey seems to be quite correct, and I already knew that it was possible to explain all the forms of Doppler effect by means of my "light quantum" conception.

By studying the collision of a moving electron with a light quantum, I have also obtained a formula for the change of frequency which involves both the Doppler effect and the Compton effect.

In a recent number of the *Phil. Mag.* (May 1924) Mr. William Anderson has stated a curious and perhaps not very probable consequence of my views.

I think that the *isolated* quantum of radiant energy can only be considered in radiations of very high frequency (when Wien's law is valuable), but that for radiations of mean or low frequencies we must conceive a sort of aggregation of light quanta. This idea suggested by the form of Planck's law would perhaps allow us to imagine a transition between light quanta and electromagnetic theory and to avoid Mr. Anderson's conclusion.

June 14. LOUIS DE BROGLIE.

Cell Inclusions in the Gametogenesis of Scorpions.

SINCE last winter I have been engaged on the study of cell-inclusions in the gametogenesis of scorpions, and it was, therefore, with some interest that I read the note of Profs. D. R. Bhattacharya and J. B. Gatenby on the spermatogenesis of an Indian scorpion (Palamnæus) published in NATURE, June 14.

I have studied mitochondria in the spermatogenesis of *Palamnæus fulvipes madraspatensis*, and can confirm the following statements of the writers :

(1) " The mitochondria are sorted out whole during the maturation stages." This is true of both the meiotic divisions.

(2) " The number of mitochondria varies in the spermatid."

In *Palamnæus fulvipes madraspatensis* the number varies from four to thirteen.

I am, however, unable to support the statement that " the mitochondria form the sperm tail directly. . . ." During a certain stage in spermateleosis the mitochondria are grouped together at the base of the elongated nucleus. To a large extent they lose their individuality and form a curious oval body—the mitosome—which stains characteristically with crystal violet, Altman's acid fuchsin and iron hæmatoxylin. I have not been able to detect the mitochondria after this stage. Nor have I seen them at any stage descending down the axial filament.

I may here add a note on the mitochondria of the oocyte of the same species. They are remarkably different in their reaction to osmic acid from those of the male germ cells. There is no case on record where the mitochondria are blackened by chrome-osmium alone. Where they are blackened, it is only after prolonged osmication (Kopsch). But the mitochondria in the oocyte are intensely blackened by chrome-osmium alone in ten hours. They are even preserved and blackened by Fleming-with-acetic acid. They can be decolorised by turpentine, but subsequent staining is impossible. They are completely destroyed by Bouin's fluid. These facts undoubtedly suggest the presence of a large amount of unsaturated fat in the mitochondria.

The Golgi apparatus in the oocyte of the same species consists of rods and crescents distributed in patches.

I hope to publish in due course a paper on the cell inclusions in the gametogenesis of Palamnæus (Madras), *Buthus judaicus* and *Heterometrus maurus* (Palestine), and *Euscorpius napoli* (Naples).

Art-Forms in Nature.

PERMIT me to thank Mr. Edward Heron-Allen for the very generous reference to my work published in his review of Haeckel's " Kunstformen der Natur " (NATURE, June 14, p. 847). Mr. Heron-Allen says: " A law only approximates to the facts, and every time we use it we have to make appropriate additions and corrections ; the real value of deviations is not that they make it necessary to discard a theory, but that they enlarge our laws and thereby advance our knowledge." This sentence formed part of an appreciation of my book, " The Curves of Life," which was published in 1914. With your permission I will quote a short passage from this book which gives an excellent example of the process mentioned, an example which in 1924 we can all read with a startling verification in our minds.

" The principle enunciated by Newton," I wrote on pp. 429 and 430, " may ' simplify ' the phenomena of our solar system sufficiently to enable us to talk about the movements of the earth and the celestial bodies. But that simplicity, we may feel sure, is only apparent. Newton himself, as far as I am aware, never ventured to suggest any ' cause ' for his great principle. We may well consider that its value as a working hypothesis outweighs the possibilities of its inexactness. But we must be equally prepared to realise that it may not fit all the facts which future science may discover. It is, in H. Poincaré's admirable phrase, *une règle d'action qui réussit* ; or, in other words, we have added (1914) so few phenomena of real importance to those known by Newton that the basis furnished by his ' law ' has not yet been disintegrated. But it is easily conceivable that a broader foundation will be needed, even in the present century ; and we need have no fear that men of science will shrink from the endeavour to provide it. The sterile reprobation of Auguste Comte (who was obsessed by sociological ideas of ' Order ') has long ago become inoperative."

These lines were written ten years ago, and I freely admit that logic had more to do than special knowledge with a prophecy which Einstein was so soon and so brilliantly to fulfil. THEODORE A. COOK.

The Oogenesis of Lithobius.

THE oogenesis of the Arthropoda is the least well understood, because it has presented considerable technical difficulties. In this country Hogben has investigated successfully the oogenesis of dragonflies, and has shown that the nucleolus takes important direct part in the production of the yolk spheres.

The oogenesis of Lithobius appears to be much like that of Hogben's examples, and is probably general for Arthropoda. Yolk formation is from nucleolar extrusion, of which two phases can be distinguished ; first, an early extrusion of particles budded off from the large central nucleolus, which retains its individuality, and, secondly, an extrusion of particles derived from the fragmentation of this nucleolus. These particles multiply both in the nucleus and in the cytoplasm. The fate of the first nucleolar extrusions has not been determined, but the later extrusions enlarge after proliferation to form the definitive yolk spheres. The Golgi apparatus behaves in the usual way, being excentric and juxta-nuclear in the youngest oocytes, then spreading out through the cell, and breaking eventually into very fine grains. The mitochondria are diffuse in the earliest stages, then become concentrated to a cloud near the nucleus ; this breaks up into a number of clusters, some of which become active centres of proliferation. These form curious round mitochondrial bodies, which later fragment, the mitochondria passing out to become evenly distributed through the cytoplasm. The clouds which did not take part in the rapid proliferation also become scattered at the same time.

A full account of the oogenesis will be published later. S. D. KING.

Artificial Daylight.

By Dr. L. C. MARTIN.

THE apparently simple question "What is Daylight?" raises at once a host of supplementary questions which are not easy to answer, and a little consideration shows that "daylight" is a word of somewhat indefinite meaning. The paper on which the present article is being written is illuminated by light from a north window. The sky is blue, but flecked with white clouds reflecting winter sunlight. A proportion of the light is, however, coming from the walls of an opposite house, and since this house is flanked by green trees and shrubs, they are also contributing their share of reflected light. A spectrophotometric examination of the light would doubtless reveal a somewhat irregular spectral distribution of energy, varying from minute to minute, although the eye registers no marked change in the appearance of the paper. Even after the drastic step of drawing the blinds and switching on the electric light, the appearance will scarcely indicate the tremendous alteration in the nature of the light, at any rate when the eye has been accustomed to the changed conditions. It is not until some effect of simultaneous contrast brings the artificial light into comparison with daylight that the difference between the two is revealed.

It is quite clear that it is useless to attempt to copy the heterogeneous radiation described above; therefore it is necessary to study the distribution of energy in the spectrum for summer sunlight and the light from a blue sky, and to see how far the means at present available will allow the production of radiation with similar characteristics. Some suitable compromise can then be decided upon. Fig. 1 shows, reduced to a common ordinate at 0·59μ, the *relative* distribution of energy in the spectrum for blue-sky light, summer sunlight, and electric light (gas-filled incandescent lamp). The gas-filled lamp radiates, as indicated by experiment, in a manner similar to a perfect radiator (the black body of the physicist) at a temperature of 2800° C. By extrapolating from experimental results, it is found that the sun radiates like a perfect radiator at about 5000° C., a temperature unfortunately quite unattainable at present in any usual and practical terrestrial source of light. It is only in intense electric discharges that such temperatures can be attained experimentally.

Amongst the special means of light production the Moore vacuum tube must be mentioned. The discharge from a small transformer passes through rarefied carbon dioxide at a pressure of about 0·1 mm., the tubes being of considerable length when used for industrial lighting. Luckiesh states that the light is a "good approximation to average daylight." Since the spectrum consists of bands, however, and is by no means continuous, this light is apt to prove untrustworthy for colour matching purposes, more especially in dealing with substances possessing bright narrow bands in the spectrum of their transmitted or reflected light.

Phosphorescence and allied effects are extremely efficient in regard to the energy required in producing a given amount of light, but under present conditions the utilisation of the phenomena for commercial light production is not practicable.

We turn, then, to consider the means of modifying the energy distribution in the spectra of ordinary sources, and before proceeding to the better known methods, two useful laboratory devices may be mentioned. Priest finds that by passing the light through a system of polarising prisms and quartz plates cut perpendicular to the axis, the spectrum of such a source as the gas-filled tungsten lamp can be modified to an equivalent of that from a black body radiating at 5000° C., and moreover, the apparent temperature of the equivalent radiator can be controlled over a wide range. The Arons chromoscope is convenient for the purpose. Another method of interest is the spectrum template of Abney and Ives, in which the radiation from the source is first dispersed

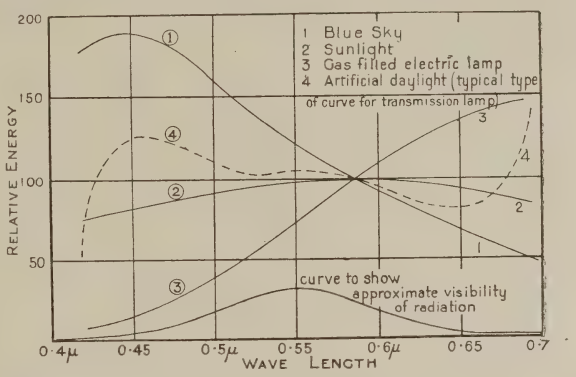

FIG. 1.—Relative distribution of energy in spectra of light sources.

into a spectrum and then recombined. In the plane of the spectrum a sector rotates, and one of the lines bounding the angular opening of the sector is curved in such a way that the effective angular aperture varies so as to be greatest in the blue and least in the red regions of the spectrum. In fact the apparent energy distribution in the spectrum of the reconstituted light can be made to follow any prescribed law.

It will be apparent, however, that the two foregoing methods are wasteful in so far as their action depends on the mere elimination of the excess energy of the longer wave-lengths.

Apart from consideration of energy distribution, however, the two methods above are quite impossible for lighting purposes, and therefore the aid of selectively transmitting or reflecting light filters or reflectors has to be employed, this expedient being suggested by Mr. A. P. Trotter some thirty years ago or so. In 1899 Dufton and Gardner produced a filter for correcting the light from the carbon arc. Though this light has an energy distribution which comes almost as near to sunlight as any artificial light (the temperature of the carbon arc is 3500° C. to 4000° C.), the flame of the arc gives an excess of violet radiation from the well-known cyanogen bands, and hence the radiation needs a special type of correction. Dufton and Gardner's glass was coloured blue-green by means of copper, and a trace of uranium gave the property of filtering out the excess of violet from the arc-light.

Since that time several types of colour filter made of

special glass, or glass in series with dyed gelatin films, have been introduced for the correction of the light from other artificial sources, namely, ordinary metal filament electric lamps, gas-filled electric lamps, and incandescent gas lamps. Lamps employing coloured reflectors have also been introduced. The gas-filled electric lamps work at a higher temperature than those of the ordinary metal filament type, and consequently the correction required to produce artificial sunlight is less drastic in the first case. The correction for an incandescent gas mantle is even less since the spectrum of the radiation is particularly rich in the shorter wavelengths as compared with the radiation from a "black body" at the same temperature.

On the whole, experience has shown that the gas-filled lamp lends itself most readily to the present purpose, and practically all the modern lamps start with this light mainly because gas-filled lamps can be readily fitted into a lantern or shade without the greater difficulties of ventilation encountered when using an arc or gas burner.

There are at present several varieties of artificial daylight lamps on the market. In the first type the lamp is enclosed in a lantern with a reflector, and the light passes through a colour filter, the glass being coloured by various proportions of cobalt, manganese, nickel, and copper. Suitable glasses have been produced by Ives and Brady, and by Gaze in America. Messrs. Chance Brothers of Birmingham have also produced a "Daylight" glass. The type of correction usually aimed at is a compromise between the energy distribution found in sunlight and blue-sky light; thus the luminous efficiency of such units considered merely as sources of light is inevitably low. In one transmission lamp recently examined by the writer the overall efficiency was only 8 per cent. as compared with the unshaded lamp, but this was employing an ordinary metal filament bulb. If a gas-filled bulb had been employed the efficiency would probably have been much greater, perhaps 12-15 per cent.; a great deal depends on the reflector, which can, if well designed, produce a considerable concentration of light, thereby counteracting the unavoidable disadvantage of the loss of light in the filter.

The glasses employed for the filters often show some deviation from the desirable smooth transmission curve. In the unit due to Lamplough a small excess of green transmitted by one blue filter is compensated by the provision of a second filter of glass slightly coloured purple by the use of gold. The purple filter absorbs the excess of green and the quality of the light is greatly improved.

A second type of lamp (the Sheringham Daylight) employs the device of reflecting the light from a surface coloured with patches of blue, green, and red or yellow pigments in definite proportions of area. The light is completely diffused, and this is a considerable advantage when imitating the effects of actual daylight. Furthermore, the energy distribution of the reflected light can be made very "smooth," although it is difficult, just as before, to secure drastic correction without undue loss of energy. The method of making a spectro-photometric comparison between natural and artificial daylight has been described by Mr. P. R. Ord in the *Illuminating Engineer* for July 1923, but there is at present very little available information on the relative performances in energy distribution and luminous efficiency of the various lamps.

The actual correction attained in all these lamps is good over the brightest part of the visible spectrum between 0·45μ and 0·65μ. At the violet end the radiation is very deficient in violet, and at the extreme red end practically all the commercial units give far too much energy (see Fig. 1). The fact that these defects do not destroy the ordinary usefulness of the lamps is owing solely to the low visibility of the radiations corresponding to extreme ends of the spectrum, as shown by the lowest curve in Fig. 1. Occasionally the error is made manifest by some material with a low reflection through most of the spectrum and a large reflection at the red end. The "artificial daylight" may then produce a different appearance in such a substance as compared with daylight itself, but on the other hand, such materials vary greatly in appearance under the variations of daylight.

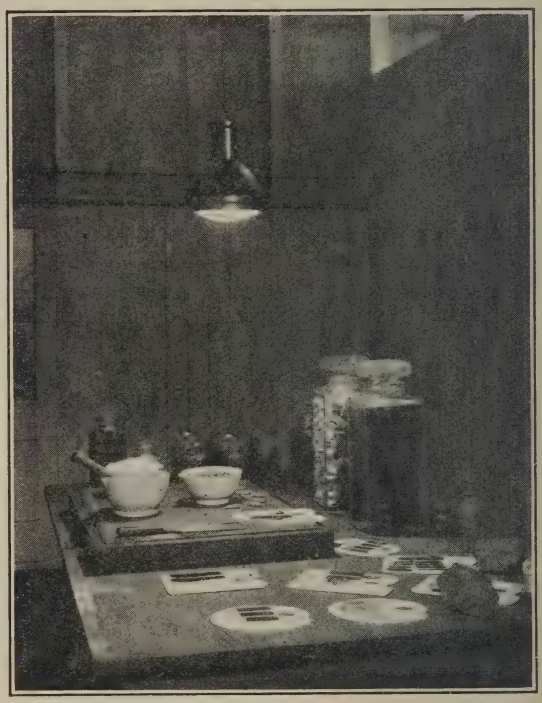

FIG. 2.—Lamplough daylamp (200-watt industrial model) in use at the laboratories of Messrs. Winsor and Newton, Ltd., for grading pigments. By courtesy of The Lamplough Daylamp, Ltd.

A third type of lamp usually employs a simple coloured bulb, either of coloured glass or coated with a gelatin filter. The correction in many of these units is not nearly so thorough, and therefore the luminous efficiency can be kept much higher, perhaps up to 60 per cent. or so. While lamps of this kind give a much better sense of relative value to blues and greens, they are of little use when exact colour matching is of importance, and recourse must therefore be made to the more fully corrected units.

Other types of lamp, of Continental origin, employ two or more colour filters. The light transmitted through these filters is mixed by diffusion.

In considering the spheres of usefulness of such lamps as are at present available, we recall first of all the considerable number of industries in which "grading" and estimations of quality of products by visual appearance are of the greatest importance. Tea, leather, tobacco, seeds, flour, and many other materials are all judged by colour, and until the modern daylight lamps were available a very great deal of time was lost owing to the lack of good daylight often experienced during the winter in industrial towns. So far as can be judged, however, artificial daylight has proved entirely satisfactory for purposes of this kind when sufficient care is employed in choosing a lamp suitable for the work in hand. A jeweller requires a strong light concentrated in a small area, and for this work one of the lamps with a focussing reflector would be best. On the other hand, for warehouse lighting a lamp giving good diffusion, such as the Sheringham Daylight, may prove the more suitable. The fully corrected lamps have been adapted for studio lighting by artists, and for counter illumination in drapers' shops and elsewhere. Fig. 2 shows a "Lamplough" transmission unit in use for grading pigments at Messrs. Winsor and Newton's.

Persons with experience of work with the artificial daylight units learn to adapt their estimations to the relatively constant light of these lamps, and less difficulty is often experienced than in working with highly variable daylight.

The "higher efficiency," and less fully corrected, lamps are applied with success for the lighting of shop windows by drapers and florists. A great improvement in colour values is secured without undue expense. The main factor militating against the employment of artificial daylight for general lighting seems to be a purely psychological one. Objection is taken to the "cold" appearance of the light when contrasted with that from ordinary lamps, but after all the matter is scarcely of importance if the corrected light is readily available when required.

It may be recalled that the difficulty of obtaining a reasonably constant standard of white light is one of the greatest difficulties in the application of colorimetry for modern industrial purposes. Stanford (*Biochemical Journal*, xvii. No. 6, 1923) has recently pointed out the usefulness of an artificial daylight lamp (the Sheringham lamp was actually used) for purposes of colorimetry with limited range colorimeters,[1] and for many chemical estimations, such as comparisons in Nessler cylinders. Artificial light corrected thus, or by a suitable filter of daylight glass, or by one of the laboratory methods described above, is of the greatest service in the more general problem of colour measurement which is being investigated with much energy in Germany and America at the present time, although the subject seems to attract little attention in Great Britain.

In conclusion, one might comment perhaps on the lack of interest shown by commercial firms in the subject of artificial daylight, and the improvement of lighting generally. In 1920 there were 15,000 fully corrected artificial daylight lamps in use in America, and the demand was then rapidly growing. In Great Britain it is doubtful whether a tenth of the American demand has been reached. The saving of time effected by the employment of such lamps in bad weather is so great that this indifference seems extraordinary, and the sooner this state of affairs is remedied the better for those industries to which this subject is of importance.

[1] See "Colour and Methods of Colour Reproduction" (Blackie), p. 114.

The Plant Commonwealth and its Mode of Government.[1]

By Sir FREDERICK KEEBLE, C.B.E., F.R.S.

TO describe in any detail the different kinds of receptor, or receiving apparatus, whereby an external stimulus of light, gravity, etc., is registered by the plant, lies beyond the purpose of this discourse. It is, however, essential to that purpose to point out that the region of reception of the stimulus is often separated by some distance from the region of reaction. Cut or burn the root of a sensitive plant, and presently the leaves begin to move. First, those nearest to the base of the stem bend down hingewise on the leaf cushion (pulvinus) and their leaflets fold together; then in succession those higher up the stem undergo a like series of changes, until all have soon reacted to the shock. Place a root on its side and its growing region an inch or so behind the tip, elongating more on the upper than on the lower side, initiates a curvature which continues until the tip points again vertically downward. But if, as Darwin showed, the tip be cut off before the root is placed in a horizontal position, no curvature occurs until a new root-tip has been regenerated. In the intervening days the root continues to grow horizontally. Cover or cut off the tip of the first leaf of a grass seedling and the actively elongating region fails to respond by curvature to one-sided illumination.

It is therefore evident that there is often a definite separation of receptor and effector region, and one of the most interesting problems in plant physiology is to discover how that gap is bridged. In animals nerves serve to connect the receptor organs—the receivers of specific stimuli—and the effector organs—the structures which respond by movement or other definite changes. But though many have sought for and some have thought to find them, those specialised conductors of excitation which are called nerves appear to be absent altogether from plants. Some have believed that the intercellular protoplasmic fibres serve like nerves to conduct impulses. It may be so, but facts are not very favourable to this interpretation of their function. It would, indeed, seem more probable that the protoplasmic intercellular strands serve to transmit not nervous impulses but materials from cell to cell.

There is, however, no need to carry these speculations further, since recent discoveries have thrown a new light and put a different complexion on the mode of transmission of excitation in plants. If a little mica plate be inserted into a cut made half way across the

[1] Continued from p. 15.

tissue of the first leaf of an oat seedling at a short distance behind the receptive tip, excitation resulting from unilateral illumination is transmitted as in intact plants. But if a second plate of mica be inserted in a second cut made on the opposite side at a slight distance from the first no curvature results; the plant remains unresponsive to unilateral illumination. Similarly, as might be supposed, if the tip be cut off completely and replaced so that it rests on a plate of mica introduced between it and the rest of the leaf, curvature does not occur. But if the tip be cut off and glued on again with gelatin, unilateral illumination induces the same curvature as it does in the intact oat leaf. The receptor apparatus in the tip suffers no damage from the operation, and undergoes the same excitation as in the normal plant. This excitation passes through the gelatin to the intact effector region and brings about in that region redistribution and changes in rate of growth which are made manifest by curvature.

There would, therefore, appear to be no escape from the conclusion that that which passes from receptor to effector regions is a stimulatory substance—a hormone. The message transmitted by the receptive tip to the reacting region is a chemical message. As a letter in the post-bag may pass many doors and cause no stir until it is delivered at the right address, so the hormone which evokes heliotropic response passes through or by many cells without, so far as is known, producing any effect upon them. It is not for their address. Only when it reaches the cells beyond the growing point which have ceased to divide and begun to grow in length and breadth does the message which the hormone bears become significant. Similar beheading and reheading experiments have been made by Mr. G. R. S. Snow in my laboratory. Although it might seem unduly sanguine to expect anything to happen after a root tip has been cut off and stuck on again, the experiment, which has now been repeated many times, demonstrates that the receptive tip, after the operation, responds to the stimulus of gravity stimulation, and that the message which provokes curvature in the growing region is transmitted across a gelatin junction. For if after replacement of the cut off tip the root is laid in a horizontal position, instead of remaining in that position as a tipless root does, it curves until the tip points once again vertically downward.

No less remarkable are the discoveries which have recently been made by the Italian physiologist, Ricca, on the much investigated subject of the movements of the Sensitive plant, *Mimosa pudica*, and allied sensitive species. The movements of this plant have often been described and always excite wonder. In tropical countries, where the Sensitive plant grows close to the ground and covers large tracts, any one who walks over it may see the leaves bending down and folding up as his foot approaches, as though the plants were shrinking from impending danger.

Many explanations have been offered of the significance of these movements; but none seems satisfactory. Extreme sensitiveness to contact is not peculiar to the species of Mimosa. It is manifested also by other genera of plants, by Neptunia, which, like Mimosa, belongs to the Legume family, and by Biophytum, *e.g. Biophytum sensitivum*, a member of the Geranium family. A recital of all the interesting experiments which have been made on *Mimosa pudica* from the time of Claude Bernard to the present day is beyond my powers or your patience. Nor is the recital necessary for my present purpose, for the new classical experiments of Ricca, and the as yet unpublished experiments made recently by Mr. Snow, throw new light on the nature of the message which passes to the leaves when the plant is stimulated as it may be by tapping, shaking, cutting, or burning a part of it. Working with strong-growing woody species in the congenial climate of Italy, Ricca has shown that the excitation set up by stimulating a part of the stem travels in the wood. Even after all the other tissues of the stem are removed the excitation continues to pass upward and to bring about progressively the characteristic movements of the leaves. If a length of stem above the point to be stimulated is killed, as, for example, by subjecting it to high temperature, the message still passes and is delivered to the living leaves above the killed region of the stem.

That the excitation is of a chemical nature is shown by cutting the stem, interposing a short tube containing water between the severed ends, and then stimulating the lower part of the stem. Even under these untoward conditions the message is delivered. The hormone, rising with the water current up the vessels, diffuses through the column of water in the glass tube and, passing into the vessels above the cut, travels along them; and at each level at which a leaf is borne, the hormone passes into the motile pulvinus and excites its tissues, so that the turgid cells of the under side of the pulvinus lose water and resilience and, becoming flaccid, no longer bear up the leaf stalk, which therefore falls like a flag at half-mast. As in old times, a knocker-up went round the town leaving his noisy message at the appointed doors, so the hormone, albeit more discreetly, travels through the watery highways of the plant delivering its chemical message as it goes.

Research, however, whilst unveiling old mysteries discovers new ones, and Mr. Snow, who has just come back from studying the behaviour of Sensitive plants in the West Indies, informs me that whilst he has confirmed Ricca's remarkable results, and has shown that the hormone which travels through the wood may be made to diffuse across a film of collodion without losing its potency, has also discovered that this is not the whole of the story. Transmission of excitation in the Sensitive plant is apparently of two kinds. There is the relatively slow transmission of a specific hormone by way of the wood vessels of the stem; but there is also a high-speed transmission, far more rapid and much less far-reaching. When this high-speed transmission of excitation is employed by the stem, the track which it follows is not that of the wood vessels, nor does it lead to movement of more than two leaves above the point of stimulation.

Mr. Snow has demonstrated the existence of these two modes of transmission by the simple device of making very gradually an oblique cut in the stem. As the knife penetrates into the deeper tissues below the cortex—which tissues are known as the phloem or bast—a drop of fluid exudes from the cut. It used to be supposed that this exudation, which escapes from

certain long tubular cells, is the sign of some hydrostatic disturbance in these cells, and that this disturbance leads to the setting up of a pressure wave which evokes the movement of the leaves. But if the knife be stayed at this point, though the water drop gushes out, nothing else happens. Let it, however, be pressed a little so that it penetrates deeper into the bast and reaches to, or almost to, the cambium, which lies between bast and wood, and suddenly the high-speed transmission takes place; in a flash, the nearest two leaves fall. If the knife be withdrawn no further excitation takes place, but if it be pushed home into the wood, the second more leisurely mode of transmission comes into play. The chemical messenger which travels into the water current in the wood vessels is released and, slowly but surely, as the transpiration current rises through the stem, leaf after leaf falls until all have shown by their position that they have received and responded to the message.

These observations come opportunely. Without them I should have been tempted to round off my discourse with a confident generalisation. The varied happenings in the plant commonwealth which I have described—the revival of powers of cell-division in wounded tissues, the heliotropic curvatures of roots and stems, the ordinary response of the Sensitive plant to shock—all are brought about by specific chemical messengers or hormones. Many other phenomena of plant response to stimulation are undoubtedly also due to hormones. May it not therefore be that the mode of government of the plant commonwealth is not duplex, like that of animals, but simplex? Whereas the integration of the animal body into an individual is the outcome of messages of two kinds, the integration of the plant body is effected by messages of one kind only. In the animal body, the two kinds are those messages transmitted at high speed along the nerves and those material messages or hormones, which are distributed by means of the blood stream. In the plant body, messages of the latter kind only are at present and with certainty known to pass to and fro between the members of the commonwealth.

Until, however, the nature of the high-speed transmission of excitation in Mimosa is explored, it would be rash to predict confidently that the fundamental difference between plant and animal will be found to lie in this, that the plant commonwealth has not and never had the means of rapid message-sending which in the animal world takes place by means of the nervous system, and that the passionless perfection of plants has been achieved solely by developing the system of special messengers. Or adopting Bayliss's metaphor: If the integration of the animal is to be regarded as due to the simultaneous employment of a telegraph system and a postal service—one for quick messages which may be of a physical kind, the other for less rapid messages of a material kind—then it may be that the integration of the plant commonwealth has been and is effected solely by the employment of the postal system. One—the animal world—partakes rather of the nature of an empire, and the other—the plant world—partakes of the nature of a commonwealth, and if so the title of my discourse needs no further justification.

Obituary.

PROF. J. G. LONGBOTTOM.

THE death has been announced, at the early age of fifty-four, of Prof. John Gordon Longbottom, of the Royal Technical College, Glasgow, which occurred on June 6 after a serious operation. Prof. Longbottom was a native of Keighley, Yorkshire, and served his apprenticeship in engineering in the works of Messrs. F. and J. Butterfield. His technical education was received at the Bradford Technical College, and a Whitworth Scholarship enabled him to proceed to the Royal College of Science and University College, London, where he became an assistant to Prof. Karl Pearson. About twenty-eight years ago he joined the staff of the Ro ya Technical College, Glasgow, and became professor of mechanics on the retirement of the late Prof. Rowden.

Prof. Longbottom was very retiring, and consequently his abilities were not widely known outside the College. His mathematical knowledge and his power of applying it to practical problems were of great advantage to his students, who will remember him not only for the soundness of his work, but also for the kindliness of his disposition. His appointment was made prior to the erection of the new buildings of the College, and he was therefore responsible for the equipment of the Materials Laboratory—an installation which is worthy of the College. He was a member of the Institution of Mechanical Engineers and of the Institution of Engineers and Shipbuilders in Scotland; he contributed to the latter Institution a paper on the stresses on the rim and arms of a flywheel.

PROF. IAN DEYL.

PROF. IAN DEYL, who died on February 4 in Prague, was born in 1855 in Vysoké Veselí nad lidlinon, and prepared himself for the duties of an all-round practical surgeon. But at last he became an ophthalmologist. I cannot dwell here on his numerous original investigations so far as they refer to medicine, of which the most interesting ones treat of the relations of eye diseases to the diseases of the body. He solved in fishes and birds the most complicated problem of the embryology of the mechanism of the eye, namely, the way in which the crossing of the eye-nerves on the lower part of the skull takes place.

Deyl was a member of the Bohemian Academy of Sciences, of the Royal Society of Bohemia, of the Ophthalmological Society, etc. He was of noble character and a great benefactor of the blind, and an institution for the blind bears his name.

BOHUSLAV BRAUNER.

We regret to announce the following deaths:

Dr. C. E. Moyse, emeritus vice-principal of McGill University, Montreal, aged seventy-two.

Sir Jethro Teall, F.R.S., lately Director of the Geological Survey of Great Britain and of the Museum of Practical Geology, London, on July 2, aged seventy-five.

Sir Harry Veitch, formerly vice-president of the Royal Horticultural Society, on July 6, aged eighty-four.

Current Topics and Events.

A CONFERENCE arranged at the British Empire Exhibition by the Royal Society for the Protection of Birds took place on June 26. The subjects for discussion were legislation for bird protection in different parts of the British Empire, the oil menace, and the formation of Nature reserves and bird sanctuaries. Overseas representatives described the conditions in their respective countries. In some of these the question of the preservation of bird life is a very urgent problem: on the one hand the changes within recent years—owing to the rapid increase of human population and all that it implies—are very obvious, while on the other hand the need for counteracting insect pests is particularly great. In some parts of the Empire, legislation on the subject is ahead of that in Great Britain, but although high penalties are imposed, enforcement of the law is often difficult. One is glad to see this subject discussed in its wider aspects, even although foreign countries were on this particular occasion not included. Owing to the seasonal movements of birds from one country to another, international co-operation in protective measures is highly desirable, and we were told at this conference how much the Migratory Birds Treaty with the United States has done for the Canadian summer avifauna. The oil menace also requires international handling, because the waste oil which nowadays causes so much cruel and unnecessary destruction of birds, as well as of fishes and other marine animals and of seaside amenities, is as a rule originally discharged at sea outside territorial limits.

AT the close of the current session, Prof. J. B. Cohen will retire from the chair of organic chemistry in the University of Leeds, severing a connexion which dates back to 1891. In that year, after some experience in the works of the Clayton Aniline Company and in the Chemistry Department at the Owens College, Manchester, he was appointed lecturer in organic chemistry and afterwards became the first occupant of the chair of organic chemistry established in 1904. To the advancement of organic chemistry Prof. Cohen has contributed very substantially in many ways. His original work has centred, for the most part, in problems connected with substitution in aromatic compounds, with the relation between optical activity and position isomerism and with the influence of chemical constitution on the antiseptic properties of organic compounds. His success as a University teacher has been in no small measure due to his faculty for lucid exposition, to his constant attention to the routine laboratory work of his students, and to his never-failing interest in the difficulties of the beginner. To large numbers of organic chemists, his name is particularly familiar as the author of widely read text-books which have played no small part in attracting students to the study of the subject. As a member of Government Committees dealing with the question of smoke abatement, Prof. Cohen has been able to supply valuable data from first-hand observations on the deleterious effects of smoke. Much of his leisure has been given up to social work, and as president of the University Working Men's Club at Leeds, he has, with much success, laboured to bring University students into contact with young working men, to their mutual advantage. In recognition of his services the funds necessary for the establishment of an annual University prize are in course of being provided by Prof. Cohen's colleagues, friends, and past students. To his colleagues, the approaching retirement is an event rendered less regrettable by the knowledge that arrangements will probably be made for him to continue his experimental work in one of the University laboratories.

A MOST interesting appreciation of Lord Kelvin, the centenary of whose birth has just been celebrated, appears from the pen of Sir Oliver Lodge in a recent number of the *Observer*. As a physicist who can enter into the spirit of Kelvin's work in a way that few others can, Sir Oliver sums up the scientific career and genius of the great pioneer with a wonderful sense of proportion. Attention is directed not only to the vast mathematical power and knowledge that he possessed and applied with such notable results to the foundations of thermodynamic and electromagnetic theory, but also to his all-compelling enthusiasm and his remarkable originality and independence of thought. "Many a German professor and some English professors," writes Sir Oliver, "were more learned than Lord Kelvin, but none were so original. . . . His métier was not to follow but to lead." This independence of thought sometimes brought him into avenues from which he was obliged to retreat. The writer pays great tribute to the practical results of Kelvin's labours. His navigational and electrical instruments are household words to-day, and many of his theories have had unexpectedly far-reaching results. He was, however, not always a good judge of his own work. Sometimes he lost his way and floundered. He was an inspiring rather than a safe and secure guide. "But," concludes Sir Oliver, "he has written his name large on the history of physical science, and all the world marvels at his genius and is thankful that he lived."

THE work of William Pengelly as a geologist and as the explorer of Kent's Cavern will always be remembered by scientific workers, and some of his papers must ever figure among the classics of geological literature. The celebration last month of the jubilee of the foundation of the Museum of the Torquay Natural History Society is a reminder of the way in which he has left a mark in the town which will keep his memory ever fresh in the minds of all who know Torquay. In 1844, Pengelly, Dr. Battersby, Mr. E. Vivian and some fifteen kindred spirits founded the Society, but it was not until 1874 that the foundation stone of the Museum was laid by the Rev. T. R. R. Stebbing, president for the year, who is still with us. In March 1894, Pengelly died and a good lecture hall was added to the building as a monument to his memory. For many years the building has been a worthy focus for the scientific thought and work of the Torquay district, a region peculiarly rich in opportunities for

research. Mr. Harford J. Lowe, the honorary secretary, speaking at a garden party held at Torre Abbey, said: "The life of the Society must be credited in a very large measure to the incomparable work, during many years, of Mr. Pengelly, who through his excavations in Kent's Cavern provided the mainstay of the Society and gave it world-wide notability." This note was echoed at a garden party given by Pengelly's daughter, Mrs. H. Forbes Julian, on the following day, and again by an account she gave to the Society of her father's work. "A man," she said, "is best judged by the work he has done, the influence he has exercised during his lifetime, and the results he has left behind for the use of posterity."

TAKING the weather records at Greenwich Observatory as a fair representation of Midland and South-east England, a consideration of the meteorological results for the first six months of the current year shows a prevalence of dull and rainy weather. The mean temperature for the six months is 0°·15 F. above the normal for the past 35 years, and whilst January, May, and June were warmer than the normal, the months of February, March, and April were colder than the normal. In May, the shade temperature was above 70° on 8 days, the highest reading being 79°; the temperature in the sun's rays was 130° or above on 14 days, the highest reading being 150°. In June, the shade temperature was above 70° on 16 days, and on 2 days it was slightly above 80°; the solar radiation temperature was 130° or above on 16 days, and the highest reading was 149°. The rainfall was in excess of the normal in all of the six months except February and March, yielding a total excess of 2·41 in.; the latter half of June was generally dry, rain only falling on 3 days after June 13. Bright sunshine was deficient in all the six months except January and March, the deficiency for the whole period averaging about a quarter of an hour per day; in April the bright sunshine was 1·66 hours per day less than the normal. Although the weather has continued somewhat unsettled there has fortunately been no recurrence of late of the abnormal conditions which continued with such persistence during the winter and early spring.

IN the *Times* of July 2, Mr. Richard O. Marsh publishes an amplified account of the previously reported discovery of "white Indians" in the district of Darien in Panama. The expedition of which Mr. Marsh was leader made friends with the Indians of the district by rendering medical aid in an epidemic of small-pox. They were then induced by an offer of the assistance of the white man against the surrounding "negroid" tribes to end their feud with the "white Indians," who, as the story goes, were either killed or driven to the mountains at the time of the Spanish occupation (1512–1517) owing to the hatred of all white people which had been aroused by the cruelties of the Spaniards. Notwithstanding a ban on their marriage and an order that all their children should be killed, the type has survived ever since. As a result of Mr. Marsh's intervention, the "white Indians" have been re-admitted to full tribal rights. Dr. Breder of the American Museum of Natural History says in a telegraphic despatch that the three "white Indians," whom Mr. Marsh hopes to bring back with him to the United States, have golden hair, blue eyes and white skins, though two have "liver spots," while their skulls are unusual, being round and quite unlike the San Blas Indian type.

To the *Empire Review* for July, Mr. Hugo Hirst contributes a thoughtful paper on the World Power Conference. He points out that power schemes require capital, and this capital can only be obtained by international co-operation. The Conference attacks this problem, and the many papers contributed by authors will be a help in finding a solution. Recent developments in the industrial world will probably determine the course of the economic reconstruction of the world. In the author's opinion, this reconstruction can already be seen to be slowly emerging. Increased international co-operation is wanted in science, in engineering, and in research. Modern industry is based entirely on science, and its continuous development is only possible through research. The great inventions such as those made by Watt and Faraday are essentially simple. To put them into practice, however, requires the expenditure of capital, and only large firms can face this expenditure. To the manufacturer, research is an economic proposition. In Great Britain the question of coal conservation becomes more pressing every year. Our easily worked reserves of coal are diminishing, and so the price of coal is increasing. The cost of fuel is a greater burden on industry than ever it has been before. The many papers read at the Conference showing how other countries are attempting to solve the problem will be of permanent value to every engineer.

AT the World Power Conference at the British Empire Exhibition, papers by Mr. J. W. T. Walsh, Mr. L. Gaster and Mr. C. W. Sully dealing with illumination were read on July 4. As Dr. C. H. Sharp, a delegate from the United States, remarked in opening the discussion, it seems an anomaly that out of the very large number of contributions to this conference only three should deal with lighting. For it is estimated that quite half of the total electrical energy produced is applied in the lighting field. Mr. Walsh's paper was concerned chiefly with the activities of the International Illumination Commission, whilst Mr. Gaster showed how these are linked to other organisations concerned with illumination from the national point of view. Mr. Sully's paper was largely statistical. He showed how the average candlepower of lamps used has progressively increased during recent years, and gave some illustrations of the great opportunities for developments in lighting. There is of course every inducement to companies concerned with the manufacture of lamps or the supply of electricity to encourage the study of illumination. But one is glad to note that this interest is not confined to the purely commercial side. It is essential that the views of experts, especially those concerned with the hygienic aspects of lighting, should be heard and that the subject should be developed on scientific lines.

THE value of the agricultural exhibit (Ministry of Agriculture) in the Government Pavilion at the British Empire Exhibition, Wembley, has been considerably enhanced by the issue of a descriptive guide-book providing a short explanation of most of the exhibits. More than a score of research institutes have co-operated in working out a definite scheme, starting with an exposition of soil problems and conditions, leading through a demonstration of methods of plant and animal improvement to problems of nutrition and pathology, and concluding with the economic aspects under the headings of Horticulture and Farming and Agricultural Economics. The guide-book does not attempt to describe each exhibit individually, but gives a short, general outline pointing out what each case is intended to demonstrate. In some instances, as in connexion with wheat breeding, virus diseases and spraying with insecticides, the principles upon which the research is based are given in some detail, to render the object of the work intelligible to the public. In other cases, as with the life histories of insect pests and the section devoted to farm machinery, attention is specially directed to the results already obtained and their application in practice. A further useful purpose served by the publication is to indicate the interdependence of the various branches of agriculture, and to demonstrate the wide range of interests involved and the widely spread efforts that are being directed towards the improvement of this great national industry.

THE Meteorological Office has an exhibit of its work in the Government Pavilion at the British Empire Exhibition, Wembley, and an account of the exhibits appears in the *Meteorological Magazine* for June. The entrance to the meteorological section is at the back of the Government Pavilion. Numerous instruments necessary for weather records and weather forecasting are on view. A continuous record is given of the direction and speed of the wind over the building obtained from a Dines pressure tube anemograph, and the intensity of the rainfall is recorded by an autographic rain gauge. A balloon meteorograph is exhibited, and there is a large working model of this to show how the results are obtained. The instrument records temperature correctly to 1° C. and pressure correctly to within a few millimetres. The walls are hung with specially prepared diagrams illustrating different branches of the work. The preparation of forecasts is demonstrated by members of the office staff and data are collected by a wireless installation from a great part of the Northern Hemisphere. There can also be seen the meteorological log kept on board H.M.S. *Thrush* when His Majesty as Prince George was in command. The importance of meteorology is evidently being increasingly acknowledged.

IN an article in the issue of *Science* for May 2, Prof. F. Cajori of the University of California disposes of some of the more or less popular legends which have grown up with regard to Sir Isaac Newton and his work. The delay of twenty years in the publication of the law of gravitation was not due to his taking 60 instead of 69 miles as a degree of latitude, but to his uncertainty as to how a sphere attracted a particle outside it. The delay of the Royal Society in publishing the "Principia" was not due to the absence of any reference in it to Hooke's previous statement of the inverse square law, but to Newton's desire to stop publication. He did not believe as Cotes, the editor of the second edition of the "Principia" did, in action at a distance, but postulated a medium requiring time to act. He did not reject the wave theory of light in favour of the corpuscular theory, but made use of the idea of ether vibrations wherever it seemed the more suitable. The authoritative works of Brewster, Horsley, and Rosenberger provide no support for these legends, but this cannot be said of the "Encyclopædia Britannica" article on Newton.

IN our issue of June 28 we recorded the tragic death of two members of the Mount Everest Expedition, Mr. G. L. Mallory and Mr. A. C. Irvine. The information then available was a brief telegram; a dispatch which tells us all that is likely to be known has since appeared in the *Times* of July 5. From Lieut.-Col. E. F. Norton's message it appears that the surviving members of the party were to leave the base camp on June 15 for the Rongshar Valley, there to rest for a short period before starting on the homeward march. All the party were suffering from the effects of the high altitude work, and no further attempt to scale Everest will be made this season. Mr. Odell, who was the last to see the two lost climbers, takes up the story and describes the events leading up to the final attempt. On June 6, Mallory and Irvine left the North Col Camp for Camp V. (25,000 ft.), and the next day they went on to Camp VI. (27,000 ft.), which had been established by Norton and Somervell a few days before. The same day Odell arrived in support at Camp V. On June 8, Mallory and Irvine appear to have started on the last stage of the journey to the summit, and at 12.50, in the course of making a survey of the mountain face between Camps V. and VI., Odell observed two figures moving on the mountain above him, a comparatively short distance from the summit. Odell then returned to the North Col, and with Hazard kept watch for the return of the climbers. As they had not returned on the following day, Odell climbed again to Camp V., proceeding to Camp VI. on the next day, but no trace was found of the missing men. To search further was impossible, and the party had to withdraw. The position in which Mallory and Irvine were last seen was determined by theodolite as 28,227 ft. Odell is of opinion that they achieved success but were overtaken by darkness on the return journey, and with this conjecture it seems we must be content.

IN connexion with an article in our issue of April 12 on foot-and-mouth disease, the statement was made that "no one believes that the disease arises *de novo*." M. C. D. Perrine, of Cordoba, Argentine, writes to ask why this belief is held when it must be supposed that diseases must at one time have originated on the earth. This is no doubt true if one is not limited to time. It is a certainty that diseases like smallpox, leprosy, plague and consumption have existed as long

as we have any historical knowledge, and probably for a much longer time. Syphilis is a disease which was formerly believed to have originated *de novo* or was brought to Spain in 1493. The more modern study of original documents has shown that this is most improbable, and there is an accumulating bulk of evidence that syphilis also is an ancient disease. The more rigorously infective diseases are studied, the more easily can it be proved that they are transmitted in succession through a long series of generations.

AT a time when there are signs of an increasing interest in algæ, algologists in all parts of the world will welcome the appearance of a new periodical devoted entirely to their science. The *Revue Algologique* is edited by Dr. P. Allorge and M. G. Hamel, of the Museum d'Histoire Naturelle, Paris, and these French algologists are to be congratulated on their energy and enthusiasm in launching a new journal. The *Revue* is published quarterly, and is obtainable from M. Gontran Hamel, Laboratoire de Cryptogamie, 63 rue de Buffon, Paris 5e; price in France 25 fr., outside France 35 fr. It will contain reviews of all algological papers, commencing with 1923, and is open for original contributions. The first part now issued is well got up and consists of 96 pages. There are several original articles in French and English.

A REPORT recently issued by the Board of Education deals with the progress of the Science Museum during the years 1921 and 1922. The Museum appears to have been much hindered by lack of accommodation, part of the collections (and particularly that relating to fishery) being stored away; while the task of transferring about half of these to new quarters gave the staff plenty of occupation, new (but inadequate) buildings having been put in hand in 1922 so as to become available in instalments in lieu of space ceded to the Imperial War Museum. In spite of these difficulties, creditable progress was made: a number of new exhibits were incorporated, including a historical collection of electrical apparatus lent by the Institution of Electrical Engineers and one illustrating the history of kinematography lent by Mr. W. Day, the series relating to light road transport and to wireless communication were specially developed, an improved system of indexing was introduced and completed, catalogues were published for the sections dealing with textile machinery, aeronautics and meteorology, and much repairing and preparation of models was carried out in the workshops. A minor piece of work of some importance was that undertaken in connexion with the Eötvös torsion balance in the Museum. To the Science Library more than 5000 volumes and 15,000 parts and pamphlets were added, and a new classification scheme was put into effect. The number of readers averaged less than forty a day. The smallness of this number is doubtless due to the fact that the library is less known to scientific workers than it should be.

THE Report of the International Air Congress held in June 1923 has recently been issued as a portentous volume of nearly 1000 pages, edited for the Committee by Lieut.-Colonel W. Lockwood Marsh (London: Royal Aeronautical Society, 1923. 25*s*.). It embodies a mass of papers and discussion on every field of aeronautical interest, aerodynamics and meteorology, engines and fuels, strength of construction, commercial aviation, legal questions, and medical problems arising out of aeronautical accidents. It is a wonderful record of achievement in so youthful a science. There were gathered together 551 representatives of 21 different nations, but the ex-enemy countries were conspicuous by their absence. This is the more to be deplored since some of the more recent and fundamental advances have been developed by the latter. An international discussion on aerodynamics without Prandtl is like relativity without Einstein. The report demonstrates the useful purpose served in effecting comparisons between the experimental methods pursued in different countries, and stresses the value of standard comparative tests in all existing wind tunnels. Contributors included members of the staffs of the National Physical Laboratory, Royal Aircraft Establishment and of the corresponding institutes in France, Holland, Italy, and the United States. The volume may be taken in fact as the most recent authoritative statement of the present position of aeronautical science both on the theoretical and on the experimental sides. The report is unfortunately marred by a number of misprints in formulæ.

SIR NAPIER SHAW, professor of meteorology in the Imperial College of Science and Technology and formerly director of the Meteorological Office, has been elected a foreign member of the Royal Swedish Academy of Science in respect of his "masterly researches on the domain of meteorology."

A SUPERINTENDENT of Fishery Investigations is required for the purpose of organising a new department of fishery research in the Straits Settlements and Malay States. Particulars of the duties of the post and forms of application may be obtained from the Private Secretary (Appointments), Colonial Office, S.W.1.

APPLICATIONS are invited for two appointments in the Department of Agriculture, Nairobi, Kenya Colony, namely, an agricultural assistant with experience in agricultural practice and ability to carry out crop experiments and to render itinerant and advisory services, and an agricultural chemist able to take charge of the chemical branch and to initiate and undertake research. Applications, upon a prescribed form, must be received before July 15 by the Private Secretary (Appointments), Colonial Office, S.W.1.

THE second annual corporate meeting of the Institution of Chemical Engineers will be held at the Hotel Cecil on Wednesday, July 16, when the president, Sir Arthur Duckham, will deliver his presidential address. During the afternoon session Sir Frederic Nathan will review the work of the Education Committee on "The Training of a Chemical Engineer." The meeting will conclude with a visit to the British Empire Exhibition, and a tour of the Chemical Hall will be made under the guidance of Mr. W. J. U. Woolcock.

THREE Agricultural Inspectors are required for the Agricultural Department, Iraq. Candidates should be honours graduates of a British university, holding a diploma in agriculture, or possessing similar qualifications. The persons appointed will be responsible for work mainly in connexion with cotton development, and there are opportunities for original research in agricultural economics. One of the selected candidates may be appointed Assistant Director of Agriculture at headquarters. It is therefore desirable that at least one of the candidates appointed should have had experience of editorial work in addition to other qualifications required.

MISS C. F. ELAM has been appointed to the research fellowship in metallurgy, of the value of 500*l.* a year for five years, given by the Worshipful Company of Armourers and Brasiers in the City of London, and awarded through the Royal Society. Miss Elam was a student of Newnham College, Cambridge, and has been engaged in research work on the properties of metallic crystals with Prof. H. C. H. Carpenter at the Royal School of Mines for the past few years. She also investigated the method of distortion of aluminium crystals in tension, in conjunction with Prof. G. I. Taylor, at the Cavendish Laboratory, Cambridge, and the results of this investigation formed the subject of the Bakerian Lecture of the Royal Society for 1923.

THE Council of the Royal Society of Arts has awarded the Society's Silver Medals for papers read before the Society during the past session as follows: (*Ordinary Meetings*)—Sir Frank Baines, "The Preservation of Ancient Monuments and Buildings"; Sir Richard A. S. Paget, Bt., "The History, Development, and Commercial Uses of Fused Silica"; Major-Gen. Sir Fabian Ware, "Building and Decoration of the War Cemeteries"; Mr. Frank Hope-Jones, "The Free Pendulum"; Brig.-Gen. Sir Henry Maybury, "The Victoria Dock District and its Roads"; Mr. T. Thorne Baker, "Photography in Industry, Science and Medicine"; Mrs. Arthur McGrath (Rosita Forbes), "The Position of the Arabs in Art and Literature." (*Indian Section*)—Brig.-Gen. H. A. Young, "The Indian Ordnance Factories and Indian Industries"; Sir Richard M. Dane, "Manufacture of Salt in India." (*Dominions and Colonies Section*)—Prof. C. Gilbert Cullis, "A Sketch of the Geology and Mineral Resources of Cyprus"; Sir Frederick Lugard, "The Mandate System and the British Mandates."

Our Astronomical Column.

ENCKE'S COMET.—This is the best known of all the short-period comets, and has been observed at every return for the last century. L. Matkiewicz has taken charge of the computations regarding it that were carried on for a long period by the late Prof. Backlund. He notes that a marked change in the mean motion took place in 1918, similar to that in 1904. Since observations in 1921 were confined to a fortnight, it is very desirable to observe the comet over a long arc at the present return. Its detection in July is possible, and it should certainly be found before the end of August.

The following elements, which include perturbations by Jupiter only, are from *Astr. Nachr.* 5298:

T 1924 Oct. 31, 429 G.M.T.
ω 184° 43′ 43″
Ω 334 · 37 33 } 1924·0
i 12 30 21
ϕ 57 48 28
μ 1074″·092

EPHEMERIS FOR GREENWICH MIDNIGHT.

	R.A.	N. Decl.		R.A.	N. Decl.
July 16.	2h 46m 37s	24° 30′	July 28.	3h 14m 57s	27° 9′
,, 20.	2 55 46	25 20	Aug. 1.	3 25 16	28 8
,, 24.	3 5 10	26 14	,, 5.	3 36 17	29 8

Values of log r, log Δ on Aug. 1: 0·2294, 0·2268. The comet is a morning object, rising 5 hours before the sun in mid July.

TOTAL LUNAR ECLIPSES.—An article by W. J. Fisher in Brit. Astron. Assoc. Journal for May gives useful hints on the observation of total lunar eclipses. These phenomena were for long regarded as of little scientific value. Then opportunity was taken to improve our knowledge of the moon's diameter by making numerous observations of occultations at the darkened limb. Afterwards it was recognised that study of the illumination of the eclipsed moon gave useful information on the average transparency of the air in the regions for which the moon was in the horizon. A map of the circumstances of the eclipse of Aug. 14 next (partly visible in England) makes it easy to locate these regions for every phase of the eclipse. They lie to a considerable extent over Europe, Africa, and South America, so that direct meteorological observations will be available for comparison with those given by the eclipse.

It is suggested that spectroscopic observations with a large lens and short focus might be made during totality; also the use of screens of various colours might enable more exact determinations to be made of the colours of various parts of the disc. The study is an easy and attractive one for amateur observers.

REPORT OF THE BERGEDORF OBSERVATORY.—This Observatory is carrying on an active programme of work in various fields under its director, Prof. R. Schorr. A second appendix to his "Eigenbewegungs-Lexikon" has just appeared, containing 1248 new proper motions, mostly of stars from magnitudes 6 to 9 and Right Ascensions from 0h to 2h; the astrographic and other recent catalogues have been used in preparing it.

The meridian work at the Observatory includes the re-observation of stars in Rümker's Catalogue, of which a revision was recently published.

Dr. Baade uses the reflecting telescope for the photography of minor planets and comets; the comet found by him in 1922 was followed until the early months of 1924. The very interesting planet 944, found by him, which travels all the way from the orbit of Mars to that of Saturn, has received the name "Hidalgo," after the Mexican hero; this is in recognition of the warm reception given to the German Eclipse Expedition to Mexico in September 1923. Masculine names are given only to minor planets with exceptional orbits, such as Eros and the Trojans.

Prof. Schorr is further engaged on the great "Geschichte des Fixsternhimmels," which contains a summary of all meridian work on the stars from 1750 to 1900. The first 2 hours have already appeared. This work was begun by Ristenpart at Berlin, but was interrupted by his departure to South America, where he died.

Research Items.

PALÆOLITHIC SKULLS FROM CAVES IN SOMERSET.—Vol. ii. part i. of the Proceedings of the Spelæological Society of the University of Bristol contains an important communication by Sir Arthur Keith, describing the skulls found in Aveline's Hole, Burrington Coombe, Somerset. This cave, as has been shown by excavations carried on by members of the Society, served as a dwelling-place—and as a burial place—for man in the closing phase of the Pleistocene period. Of the three skulls described, one is dolichocephalic and two are brachycephalic. Notwithstanding this difference, Sir Arthur Keith is of the opinion that they belong to the same race, the variation in length-breadth index being negligible in view of the identity of other characters, notably the high-pitched cranial vault. In this respect they compare very closely with the new Solutré crania and the Chancelade skull. Their discovery is peculiarly worthy of note, as no brachycephalic skulls of palæolithic date have hitherto been found in England. Although they differ in outline very decidedly from the late palæolithic skulls found both at Ofnet and Furfoos, yet in absolute length and breadth they show a close correspondence to those from the latter locality, while at least four of the intermediate series from Ofnet are comparable to them. Sir Arthur Keith regards them as of Azilian date, but Mr. J. A. Davis in his third report on the excavations, which appears in this issue of the proceedings, holds rather that the Aveline's Hole culture represents an isolated survival of Aurignacian into the late Magdalenian times, to which the occurrence of a typical harpoon, previously reported, seems to point.

MOURNING CAPS OF MURRAY RIVER NATIVES.—Mr. Edgar R. Waite, Director of the South Australian Museum, directs attention in vol. ii. No. 4 of the Records of that institution to a point connected with the mourning caps of the Murray River Natives which has hitherto escaped notice. The mourning caps worn by the widow, relatives of the deceased, and others, after a death, were built up of moist clay on the foundation of a net placed on the head of a mourner, usually said to be shaved for that purpose. Such mourning caps were, naturally, adapted to the shape of the head of the wearer, and also show traces of the process of building up, which was done gradually at different times. These were placed on the grave after an interval. There are, however, other forms of mourning caps which show no trace of having been built up on a foundation, and have obviously been made in one operation; also the interior is neither deep enough nor of the shape to fit on the head. It is suggested that they were dummies which were placed upon the grave by those relatives and others who had ceased to wear a clay cap as a sign of mourning, as the widow continued to do, but still used them in their dummy form as a ceremonial mark of respect to the deceased.

THE ANTS OF KRAKATAU.—In *Treubia*, vol. v. Nos. 1-3, Feb. 1924, Prof. W. M. Wheeler describes a collection of ants made during 1919–21 on Krakatau and adjacent islands and sent to him by Dr. K. W. Dammerman. During the great volcanic eruption of 1883 the fauna and flora of Krakatau, Verlaten, and Lang Islands were completely destroyed, and even Sebesi, at a distance of 15 km., seems to have suffered a similar fate. The study of the animals and plants that are gradually repeopling the islands has received considerable attention. In so far as ants are concerned, it appears that Dr. Dammerman has nearly doubled the known forms from Krakatau, and has much more than doubled the number of those known from Verlaten. The previous collector (Jacobson in 1908), however, used less refined methods of collecting so that the increase may not be entirely due to more recent arrivals on the islands. Most of the ants in the Krakatau group are common species of a wide range in the Indomalayan or even in the Neotropical region. They are hardy forms which survive anywhere in warm countries. Dr. Dammerman believes that many insects may have reached the islands as eggs, larvæ or pupæ, on drifting wood or plants, but contends that dispersal by air plays a more important part than is usually attributed to it. It is significant in this connexion that only one species of ant with wingless females is recorded by Prof. Wheeler in the collection; this evidently supports Dr. Dammerman's opinion.

ENTOMOSTRACA FROM COLORADO.—G. S. Dodds describes the Entomostraca collected by Dr. H. L. Shantz in 1903 and 1904 on the slopes of Pikes Peak (10,000 to 12,000 ft.) and from ponds on the plains near Colorado Springs (6000 to 7000 ft.) supplemented by other records from the State of Colorado (Proc. U.S. Nat. Mus., lxv.). Situated astride the Continental divide, Colorado is the meeting-place of eastern and western faunas, and includes portions of five life zones. The 31 species of Entomostraca found by Shantz fall into three natural groups: 13 found on the plains but not on the mountains; 9 found only on the mountains; and 9, able to live in both warm and cold water, found in both groups of lakes. A similar tripartite division was observable in those collected in Colorado by the author. A graphic representation of the altitudinal range of these species is given, and the author dwells on the significance of these records, especially when it is remembered that the extremes of the two groups of lakes are separated at the most by not more than 10 miles, and yet support Entomostracan faunas as distinct as if separated by hundreds of miles in a north and south direction. The several species common to the two groups stand in strong contrast to the others, and serve to emphasise the fact that temperature may be an effective barrier for some species, but not for others. The paper concludes with a list of the lakes and the species of Entomostraca found in each, with other details.

FEEDING AND DIGESTION IN NEPHROPS.—C. M. Yonge (*Brit. Journ. Exp. Biol.*, vol. 1, pp. 343-389, 1924) gives an account of the mechanism of feeding and the process of digestion in *Nephrops norvegicus*. He describes the anatomy, histology and mode of action of the various parts of the alimentary tract, and records that the enzymes of the hepatopancreas digest starch, glycogen, sucrose, maltose and lactose; the amylolytic ferment finding its optimum in a neutral medium at a temperature of 57° C. The hepatopancreatic secretion also contains a fat-splitting enzyme and a powerful proteolytic enzyme. As in other crustacea, the hepatopancreas stores fat and glycogen, but apparently not calcium.

THE LARVÆ OF THE PEA CRABS.—The zoea larvæ of the pea crabs (Pinnotheridæ) have been studied by O. W. Hyman (Proc. U.S. Mus., vol. 67, Art. 7, 1924) at Beaufort, North Carolina. Ovigerous females were collected and kept in the laboratory until hatching of the eggs took place. The eggs hatch at nightfall. The only feature that is common to the zoea larvæ of this family and serves to distinguish them from the zoeæ of other families is the minute

size of the antenna. In other families the arrangement and size of the spines of the carapace are usually distinctive features of the zoea, but in pinnotherids there is no uniformity in this respect; spines may be prominent or entirely absent. The author gives a key to the known zoeæ. The complete history of metamorphosis has not been followed in any species, but it seems probable that the pinnotherids have at least three—probably four—zoeal stages followed by a megalopa and by the young crab.

TERTIARY CIRRIPEDIA FROM HAITI.—The specific distinctions in Balanus being based upon the opercular plates, no species can be well established until these are known. In their absence the characters of the walls and basis have to be relied upon, and in forms from a restricted area fairly satisfactory results can thus be obtained. Working on these lines, Dr. H. A. Pilsbry describes three forms from the Miocene of Haiti (Proc. U.S. Nat. Mus., lxv.), of which one is doubtful, one described as a new subspecies, and the third as a new species. At the same time, he admits that in the absence of the opercular plates comparison with European Tertiary species is impossible.

PŒCILOZONITES, RECENT AND FOSSIL.—Those interesting land snails belonging to the genus Pœcilozonites are peculiar to Bermuda, and though the living forms have long been known, it is only within comparatively recent years that the fossil ones have been studied. Some of these fossil forms are now dealt with by Dr. H. A. Pilsbry (Proc. Acad. Nat. Sci. Philad., lxxvi.), who proposes two new subgenera: Gastrelasmus for the species having a long, entering palatal lamella, type *P. circumfirmatus* (Redfield), and Discozonites, type *P. blandi*, n.sp. Several new species and varieties are described and illustrated by text figures. Lieut.-Col. Peil, who has recently written on the same subject, states, however (Proc. Malac. Soc. Lond., xvi. pp. 18, 19), that in the living *P. circumscriptus* the internal lamella is sometimes absent.

IMPORTANCE OF MANGANESE IN PLANTS.—J. S. McHargue (*Journ. Agric. Research*, xxvii. No. 6) claims to have obtained data showing conclusively that manganese is an essential element in plant economy and performs an important function, perhaps catalytic, in the synthesis of chlorophyll. Other experiments are being conducted to discover whether manganese is also a vital factor in animal nutrition. In view of the results obtained, and also of the fact that manganese is found in greater quantity in those plant and animal tissues which are richest in vitamins, the author is led to assume that a relationship exists between this element and the vital factors contained in these tissues.

STATISTICS OF INDIAN WHEAT PRODUCTION.—The importance of the application of statistical methods to agricultural problems is exemplified in an article on "Wheat Forecasts in the Punjab" (H. K. Trevaskis, *Agric. Journ., India*, xix. Part III.). Originally crop statistics were based on the requirements of the land-revenue system, but the abnormal conditions created during and after the War led to the development of statistical methods of estimating whether the stocks of wheat in hand were sufficient to feed the great Indian population. At the present time the Punjab wheat statistics, with their bearing on the possibility of export, are of direct importance to the Liverpool wheat market. Forecasts are prepared, of which the first two deal only with the area covered by wheat and cotton, and the last two are estimates of the quantity of the crop actually to be handled. The various methods of estimation of crop yield are discussed, together with the statistical possibilities of estimating the amount required for home consumption. It is suggested that if a census of the stocks in hand could be made at the end of the financial year, it would be increasingly possible to estimate the accuracy of the figures for crop yield and consumption, thus providing more trustworthy data to be considered in controlling the disposal of the wheat crop.

NIGERIAN COAL MEASURES.—Bulletin No. 6 of the Geological Survey of Nigeria deals with the Nigerian Coalfields. Section 1, Enugu Area, is by A. D. N. Bain, with appendices by R. Bullen Newton and Prof. A. C. Seward (London: Crown Agents for the Colonies, 1924. 10s. net.) It shows that there are a considerable number of thin seams, but in most of the localities there is a seam of 5 ft. to 6 ft. in thickness, which is evidently workable. A number of analyses are given, showing that the coal is a non-caking coal fairly high in volatile matter and with only moderate ash contents. It is, however, possible that some of these coals may be found to produce a useful coke under suitable conditions. Apparently the coal is a good flaming coal and, therefore, well suited to reverberatory furnace work, so that it would appear to be quite possible to smelt locally the tinstone produced. The total output in 1922 is given as 110,785 tons, and it is shown that the development of collieries in this portion of West Africa is likely to be of very considerable economic importance.

COMPUTATION OF ESTUARY TIDES.—A paper entitled "Estuary tides: a comparison of methods of computation," by Dr. Bell Dawson, the Superintendent of the Tidal and Current Survey of Canada, is given in No. 41 of the Bulletin of the National Research Council, Washington. The subject under discussion is the accuracy of prediction of the times of high- and low-water at stations where the tides are much affected by the presence of shallow water, as at Quebec. The mechanical harmonic prediction as hitherto used for Quebec, though based on the analysis of 19 years' records, gives average errors in high- and low-water times of 26 and 10 minutes respectively. For Father Point, a station 180 miles nearer the ocean, the predictions are similarly based on 15 years' records, and the corresponding average errors are each 6 minutes. To improve on the predictions for Quebec, Dr. Dawson has applied his principle of variable differences, periodic (though not in general harmonic) in the synodic, anomalistic and declinational months. This is a principle which he has used extensively for many years to deduce tidal predictions at a large number of stations from the harmonic predictions for a small number of standard ports. In his present investigation, he regards Quebec as a secondary port having Father Point for its standard, whereas previously Quebec had been regarded as a standard port. By this means the average errors in the predicted times of high- and low-water at Quebec are reduced to practically the same as those for Father Point.

IONISATION IN SOLUTIONS.—In recent years the view has been expressed by several investigators that strong electrolytes are practically completely ionised even at moderate concentrations, and that variations usually put down to varying ionisation are due to varying activities of the free ions. Attempts have been made by Milner to relate the activity to the electrostatic forces between the ions, and, more recently, by Debye and Hückel. In the May number of the Journal of the American Chemical Society Prof. A. A. Noyes gives an elementary deduction of the formulæ, and a comparison with experiment. The

individual behaviour of different ions, in contradiction to the theory, again emerges, but the general agreement is of a very striking character.

ATMOSPHERIC POLLUTION.—In addition to the completed results published in the annual report of the Advisory Committee on Atmospheric Pollution, arrangements have been made for the circulation, month by month, of abstracts showing the records from deposit gauges, so that earlier information can be obtained. The results for April, according to the *Meteorological Magazine* for June, show that in the centre of Liverpool the deposit amounted to 34 gm. per square metre, while on the outskirts of Southport the deposit was only 2 gm. per square metre. In the City of London it was $13\frac{1}{2}$ gm. per square metre. Abstracts can be obtained from the Atmospheric Pollution Committee, 47 Victoria Street, S.W.1.

A NEW SOURCE OF SHORT ELECTRIC WAVES.—The second pamphlet issued by the State Electrical Research Institute, Moscow, is an account by Mrs. A. A. Glagolewa-Arkadiewa of a new method of producing short electrical waves ranging from 0·125 mm. to 50 mm. in length according to the materials used (see also NATURE, May 3, p. 640). This range includes the wave-lengths 2-4 mm. recently produced by Nichols and Tear (*Physical Review*, vol. 2, 1923), and covers the gap between them and the longest produced by Rubens and Baeyer, 0·2-0·34 mm., a dozen years ago by the method of residual radiation. The new method consists in interposing in the spark-gap of the exciting induction coil a paste of fine aluminium or brass particles mixed with heavy machine oil which is carried on the rim of a wheel like a rubber tyre. The wheel dips into a tank of the paste, and by its revolution the paste in the spark-gap is continually renewed. The waves sent out have sufficient energy to allow their wave-lengths to be measured by the mirror method of Boltzmann.

ESTIMATION OF RADIOACTIVE SUBSTANCE BY γ-RAYS.—Dr. W. Bothe describes, in the *Zeitschrift für Physik* for May, observations made at the Reichsanstalt with an apparatus in which varying thicknesses of lead, in the form of a series of concentric hollow cylinders with a total thickness of 11·0 cm., can be interposed between the preparation, which is placed in the axis of the smallest cylinder, and the ionisation chamber. This is a cylindrical sheet iron vessel, with a central cylindrical hollow space having the same radius as the largest lead cylinder, which fits into it. The inner electrode of the chamber is a cylindrical ring of sheet iron concentric with the lead cylinders, and is connected with a gold leaf electroscope on the top of the chamber. The arrangement is very sensitive, so that good readings can be obtained with the full thickness of lead. The absorption coefficients of the γ-rays from the substances to be investigated, in equilibrium with their disintegration products, are 0·50 cm.$^{-1}$ for radium, 0·62 cm.$^{-1}$ for mesothorium, and 0·46 cm.$^{-1}$ for radiothorium; so that it is possible for a mixture of the last two to behave like pure radium, and it might be concluded that it is impossible to distinguish between these two cases by the absorption method. Curves have, however, been prepared, showing the relation between the radium equivalent for the pure substances, and for different mixtures, and the varying thicknesses of the lead filter; in these the "normal value" of the preparation, obtained through 0·5 cm. of lead, was taken as unity. The curves show that it is possible to estimate the amounts of the constituents in any mixture of two of these substances, since even with a mixture of mesothorium and radiothorium, in which the absorption is "equal" to that of radium, the curve is not identical with that of radium, but cuts it at three points, and is easily distinguished from it. Such a mixture together with radium may give a curve from which it is impossible to deduce the relative amounts of the three constituents; but, apart from this, the composition of any mixture of these substances can be estimated from its curve.

WASTE HEAT BOILERS AND VERTICAL RETORT GAS INSTALLATIONS.—Results of tests carried out by the Gas Investigation Committee of the Institution of Gas Engineers at the works of the Birmingham Gas Department, and embodied in the twelfth Report submitted by the Committee to the annual meeting of the Institution, show that by the introduction of the practice of heat-recovery from waste gases in waste heat boilers the thermal efficiency of gas production in normal working with continuous vertical retorts is increased from 60 per cent. to about 66 per cent.

PULVERISED FUEL.—A paper on "Pulverised Fuel and Efficient Steam Generation" read by Mr. D. Brownlie before the Institution of Electrical Engineers last December has already been noticed in NATURE, January 12, p. 62. The paper in full with the discussions which have followed at various centres appears in the Institution's Journal for May. These are interesting because the subject of the relative merits of mechanical stoking and pulverised fuel firing is to-day very controversial and was extensively debated by many speakers. Furthermore, the paper dealt with a single system using a central pulverising plant, and there were a number of advocates of systems employing "unit pulverisers" to each furnace. Again the possibility that the ejection of coal ash would cause a dust nuisance in the densely populated areas of Great Britain aroused much concern. It was urged in reply that this dust is so fine as to be carried far away from the installation so that its final destination is unknown.

PRODUCTION OF TOWNS' GAS BY THE REGENERATIVE GASIFICATION SYSTEM.—A plant for the production of towns' gas from coal by the regenerative complete gasification system introduced by Messrs. M. W. Travers and Clark, has been in operation at Aylesbury since February 1923, and was described at the annual meeting of the Institution of Gas Engineers. The installation has about three times the output of a carburetted water gas plant which previously occupied the site on which it has been erected. Coal is carbonised in an upper section of the plant by internal heating effected by direct transference of heat from hot gases passed through the coal. The resulting coke is gasified by the alternate action of steam and air in the lower section of the generator. Heat is recovered from the blow gas in a regenerator, from which the heated circulating gas passes to mix with the water-gas passing from the lower to the upper section of the plant during the run. The output of gas from the plant is approximately 184 therms of gas of calorific power about 360 B.Th.U. per cubic foot per ton of dry coal gasified. By carburetting, the calorific power of the gas is raised to 420 B.Th.U. per cubic foot. The overall efficiency of the complete gasification process is 55·3 per cent., which compares favourably with an estimated efficiency of about 46·7 per cent. characterising the more usual practice consisting of a combination of a carbonisation process with the production of water gas. Operating charges, excluding cost of coal but including costs of carburetting and purification, amount to 1·39*d*. per therm delivered into the gasholder.

Relativity at the International Congress of Philosophy, Naples.

SINCE the inception of the International Congresses of Philosophy in 1900, it was arranged that such gatherings should be an opportunity for philosophers and men of science to meet on common ground for discussion. Nowadays, philosophers cannot claim to have a complete system unless they account for the various branches of science in their synthetic explanation of things. They must understand what men of science have found out for themselves and give a value to their discoveries in their theories of knowledge. It is quite appropriate then that they should be helped in their efforts by the searching analysis scientific workers have made of their own labours. There cannot be any antagonism between philosophy and science; one completes the other and each is strengthened by the support of the other.

It was a gratifying spectacle to see metaphysicians, logicians, mathematicians, physicists, and biologists sitting together in the great halls of the University of Naples. These meetings formed an integral part of the International Congress of Philosophy, which was arranged at Naples at the beginning of May, under the presidency of Prof. Aliotta, on the occasion of the seventh centenary of the foundation of that University.

Unavoidably the outstanding question under discussion during these joint meetings was Einstein's theory of relativity. Prof. Einstein was, however, prevented from attending the Congress at the last moment. Nevertheless, some valuable papers were read at the sittings of the section of History and Philosophy of Science. Under the chairmanship of Prof. Marcolongo of Naples and then of Prof. Hadamard of Paris, various aspects of the theory of relativity were developed. Prof. Cartan (Paris), in a paper on "The Theory of Relativity and the Generalisation of the Notion of Space," gave an interpretation of Einstein's tensor by means of the notion of curvature and that of the torsion of a curved space, using also Levi-Civita's definition of parallelism. Prof. Hadamard put forward some interesting considerations on the equations of cylindric waves already studied by Volterra. M. Nordmann, of the National Observatory of Paris, dealt with the controversy between Einstein and Bergson with reference to the relativity of time. He contended that Einstein's memoir, published in 1905, gives no ground for criticism, and that Bergson's remarks are based on certain statements, made by Einstein in his popular work, which are open to controversy.

Mr. Zaremba of Cracow, in a paper, "The Theory of Relativity and Experience," pointed out some logical failures of Einstein's theory, and expressed the opinion that at the present stage it cannot be said that experience is for or against it. Prof. Kopff (Berlin) developed some suggestive relations between astronomy and Einstein's conceptions.

Prof. Enriques (Rome), in a paper entitled "A Criticism of the Notion of Time," maintained that time is not only, as according to Kant, the order of internal sensibility, but also that it contains the idea of a natural standard of measure. The analysis of the postulates referring to such a standard reveals the unity of physical forces and the hypothesis that time is independent of space. The rejection of this hypothesis leads to the theory of relativity. Prof. Giorgi acknowledged that the mathematical and logical structure of Einstein's theory is absolutely perfect and quite compatible with natural phenomena. But he does not think that this theory has had sufficient verifications in proportion to its importance and ambitions. Prof. Severi expounded a new method of arriving at Lorentz's classical formulæ by means of an analysis of the concept of time. Prof. Timpanaro, speaking on "The Value of the Theory of Relativity," proposed a new theory, which he called etheral-ballistic, according to which natural phenomena can be explained with as much exactness as with the theory of relativity.

The great opponent of Einstein's ideas was Prof. La Rosa, of Palermo, who spoke on "Some Astronomical Facts against Einstein's Theory based on Ritz's Hypothesis." He showed how to explain several phenomena of variable stars according to Ritz's hypothesis where the velocity of light is compounded with that of force. Einstein's theory, he said, is only one of the possible relativistic ways of interpreting natural phenomena. There is, besides, what he called the "ballistic method," which has much experimental evidence in its favour. The ballistic hypothesis states that the velocity of light can be compounded with that of its source; and when applied to the theory of the double stars it leads to some very interesting and unexpected results. For example, on the basis of the ballistic hypothesis, all double stars having a distance and a period satisfying certain limitations, must appear to us as variable stars. Following up this line of thought, Prof. La Rosa offers a general explanation of the phenomena of double and variable stars.

Among other papers on the philosophy of science, we must mention those of Prof. Vorovka (Prague) and Sittignani, who discussed from different angles Poincaré's epistemological theories, and Prof. Driesch's communication on "The Philosophy of Organic Life." Prof. Hans Driesch, the most authoritative representative of vitalism, explained, with an abundance of examples, that the phenomena of life cannot be accounted for simply by means of physico-chemical processes. Biology shows us that a multicellular organism can be divided up into many parts without stopping its development. A machine cannot be submitted to the same operation with the same results. There must be, therefore, in every living organism a cohesive agent, which he calls "entelechy," the function of which cannot be analysed at the present stage of science, but obviously it causes the organism to develop whatever be the mishaps it may suffer.

In his paper on "The Specification of the Straight Line," Dr. T. Greenwood developed the logical arguments which lead him to state in a new way the problem of the characterisation of the Euclidian straight line by means of a single axiom which he calls "The Postulate of Null-Curvature." He establishes this postulate by means of a new hypothetico-deductive system of axioms based on the notions of "point" and "distance," and uses it to prove the two ordinary postulates of the straight line. This method, which is very simple in itself, has many advantages in the logical, the pedagogical, and the scientific field.

The numerous papers, more than two hundred, read at the Naples Congress did not permit of any discussion, mainly because the time available was not proportionate to their number. This, however, shows admirably the passionate devotion with which Italian thinkers study science and philosophy; and the more so as, besides the International Congress of Philosophy, an Ophthalmological Congress, a Gynæcological Congress, and a joint meeting of the Association of Scientific Societies of Italy, were sitting concurrently at Naples, whilst there was a Sociological Congress and a Eugenics Congress at Rome, and a Geographical Congress at Genoa. Yet, to all those who were able to go to Naples—unfortunately there were not many visitors from Great Britain—the visit will rank among the most pleasant memories of their academical career.

THOMAS GREENWOOD.

The National Physical Laboratory, Teddington.

ANNUAL INSPECTION.

ON Tuesday, June 24, the General Board of the National Physical Laboratory made the annual visitation to the Laboratory. As is usual on this occasion, a large number of members of scientific and technical societies and institutions, members of Government departments and of industrial organisations were also invited to the Laboratory, the whole of which was open for inspection. The visitors were received by Sir Charles Sherrington, chairman of the General Board, Sir Arthur Schuster, chairman of the Executive Committee, and the Director of the Laboratory.

An extensive programme of exhibits had been arranged to illustrate the general character of the work of the Laboratory in addition to features of particular or novel interest.

In the Aeronautics Department the wind channels were shown in operation on various problems which are engaging the attention of the Department. In the 7 ft. wind channel, the airflow round a monoplane aerofoil was being investigated with the object of examining the fundamental assumptions of the Prandtl theory of vortex motion. Special hot wire anemometers, in which the wires are placed along instead of across the air stream, are used to observe the direction and velocity of the air stream. The existence of eddies behind cylinders in an air stream was made evident audibly, by the amplification in a two-valve amplifier and telephone receiver, of the fluctuating potential differences produced by the cooling effects of the eddies, in a hot platinum wire placed behind the cylinder. In the 14 ft. channel, apparatus was on view designed and constructed in the Department for measuring the head resistance of stream line bodies in a wind channel and in the William Froude National Tank. By using the same apparatus in both air and water, the method eliminates the interference between the apparatus and the body under test, so that comparison of the results is possible, and for the first time accurate deductions of the importance of "eddies" in channel work can be made. Other exhibits included the whirling arm and the electrical method of determining the theoretical stream lines for an inviscid fluid moving past a flat plate, both of which were mentioned in the description of the exhibits at the last visitation.

In the Engineering Department, a special electrical dynamometer designed to produce full torque from 20-1700 revolutions per minute was exhibited. The field magnet frame was mounted on roller bearings, and it is claimed that the power transmitted (up to 100 h.p.) is measured to one-tenth of 1 per cent. Another interesting exhibit was that of apparatus for measuring and recording the relative movement of chassis and axles in vehicles. This work has developed in connexion with a general research on springs for vehicle suspension. The effect of shock absorbers in damping vibrations has also been investigated. Apparatus for determining the effect of keys and keyways on the endurance of shafts and for testing brake lining materials was also on view.

In the Metallurgy Department a high frequency induction furnace was shown in which metals can be melted in vacuo without danger of contamination from circumambient gases. The electrolytic preparation of iron and chromium of 99·98 per cent. purity was also on view. In the Wernher Building, interesting microphotographs showed the behaviour of mild steel and brass under the action of cutting tools. These indicated the great importance of the orientation and shape of the tool in determining the ease with which the metal is cut, the character of the finished surface and the wear on the tool.

In the William Froude National Tank a model 10-knot single-screw cargo steamer was shown under test for propulsive efficiency. The thrust and torque of the propeller and the resistance of the hull in water are measured. The plant for making accurate models of ship hulls of a mixture of paraffin wax and beeswax, and also of screw propellers, was on view, and a model propeller was shown under construction.

In the Metrology Department standard weights, including new weights made of stellite, were shown. Various measuring machines designed and constructed in the Department were also on view. These included the "millionth" comparator and tilting level comparator for the comparison of standard length gauges to an accuracy of a millionth of an inch, an improved travelling microscope and the Blythswood diffraction grating ruling engine. Various methods of the application of interferometry to metrological work were shown together with sources of light producing a series of monochromatic rays covering a wide range in wave-length.

A very large number of exhibits was shown in the Physics Department, including a new form of all-metal mercury vapour pump, capable of extremely rapid exhaustion, and a standard optical pyrometer of the disappearing filament type for use up to 3000° A. The most interesting were in connexion with the sound section, in which a photographic method of studying the acoustical properties of rooms was shown. A vertical section of a model of a building was placed horizontally in a trough of water, and trains of water waves were emitted from a point corresponding to the position of a speaker. By projecting light vertically through the glass bottom of the tank, the shadow picture of the disturbance at the surface of the water could be seen on a screen above. This was photographed at certain definite times, enabling the progress of any wave to be followed in its travel across the model of the room, and in its reflections (echoes) from the walls or architectural details. The results have shown in a very convincing manner how in buildings the structural details can interfere with the propagation of speech in certain parts, and the department has been able to make valuable suggestions to improve the acoustical properties. Experimental sounds are very often produced by electrical methods, and an interesting method of study of the purity of the waveforms of electrical oscillations, which are later transformed into auditory oscillations, has been developed. It involves the use of the Weston cathode ray oscillograph, the spot of which describes a circle on the fluorescent screen if the oscillations are sinusoidal.

The Radiology Section exhibited apparatus for the determination of absorption co-efficients, using a metal X-ray tube of high output, for the rapid determination of the lead equivalent of X-ray protective material, and various apparatus for the determination of the crystalline structure of metals and alloys, several of which have been worked out and are of great interest in connexion with the collateral work of the Metallurgy Department on the same alloys. In the Optics Section a new flicker photometer for comparing lights of different colours and improved spectrophotometric apparatus were shown. A constant temperature room has been added to the equipment of this section since the occasion of the last annual visitation and should result in the eventual determination of important optical constants to a greater accuracy than has been possible hitherto. The room is cooled by air from a refrigerat-

ing plant or warmed by air passing over electric heaters; cooling or warming to any desired temperature is automatic through electrical resistance thermometers and relays, and maintains the temperature at any point constant to 0·01° C.

In the Electricity Department, Alternating Current Division, the arrangements for the accurate measurement and calibration of A.C. instruments and of high voltage insulating materials were shown. An interesting phenomenon in dielectric hysteresis was exhibited in which a rotating electric field caused a cylinder of celluloid to rotate. The greater the energy loss due to imperfection of insulation quality, the greater is the torque and the speed at which the insulation material will rotate, except that owing to friction the speed cannot reach that of the rotating field (50 r.p.m.). In the Direct Current Division the association of a hydraulic pressure with endosmosis was exhibited. An electric circuit of 100 volts was earthed under a glass funnel full of damp earth surrounded by water. In the experiment shown, the passage of a few milliamperes caused the water to ascend from the earth to a height of 12 ft. in a tube connected to the funnel. The phenomenon is of interest and importance in the choice of the most suitable methods of earthing electrical machinery and power cables.

The Photometry Division showed exhibits illustrative of the careful work and research which is contributing to the improvement of artificial illumination of all kinds. The experimental building for determining the best methods of utilising daylight was also shown in operation, and a new instrument for measuring daylight factors shown. In the Electrical Measurements Division apparatus showing the accuracy which has been developed in the measurement of frequency in radio oscillations was exhibited. A radio station for the transmission of standardised frequency has been equipped and was open for inspection. In the Wireless Division, apparatus was shown which enables the direction of both the electric and magnetic forces in electromagnetic waves to be determined separately, so that the direction of the wave front is accurately known. This is of interest in connexion with the Beveridge antenna, the action of which is due to the existence of tilt in arriving electromagnetic waves. Among the standard testing apparatus demonstrated were a panel for measuring all the static characteristics of receiving valves, and a set for examining the amplifying properties of audio frequency intervalve transformers. In the latter arrangement the actual voltage amplification produced by a stage comprising one valve and one transformer is measured by a comparative audibility method at any frequency from 250-4000 cycles per second. Using standard types of amplifying valves this measurement enables a study to be made of the frequency distortion introduced into speech-frequency amplifiers by the iron cored intervalve transformers. Other apparatus was shown by which the input and output of any standard type of amplifying detector can be measured, thus enabling a complete study to be made of the behaviour of an amplifier at either radio or audio-frequencies. H. B.

The Natural Resources of Russia.

THE Transactions of the Committee for the Study of Russia's Natural Resources, attached to the Russian Academy of Science, include works of varying type:

(1) Separate monographs—"Precious Stones of Russia," by A. E. Fersman; "A Household Fungus," by I. A. Makrinoff.

(2) Studies of Russia's natural resources—"Russian Wax," by N. M. Koulagin; "Medicinal and Tanin-producing Plants of the Tavricheskaya Province," by B. N. Lioubimenko; "Tea and its Cultivation in Russia," by the same author; "Kendyr (Apocynum Sibiricum Pall)," by I. A. Rajkova; "Russian Sources of Fuller's-earth," by A. E. Fersman; "Beet," by E. V. Kostezky and E. J. Zalensky; "Iodine Containing Lakes of the South of Russia: Eltonskoe, Bakou Iodine Lakes and the Saki Lakes," by N. N. Efremoff, G. G. Ourazoff, and A. E. Fersman; "Bozon," by V. G. Khlopin; "Absorbing Properties of Russian Clays," by P. E. Zamiatchensky; "The Caspian Pilchard," by B. I. Meisner; "Phosphates of the Ukrain," by V. N. Chervinsky; "Tihvin Bauxite," by A. D. Stopkevitch, V. I. Ikskul, and B. P. Ovsiannikoff; "Honey," by I. A. Kabloukoff; "Mica," by I. I. Ginsbourg.

(3) Periodicals—vol. i. of "Wind as Driving Power," by M. M. Rikacheff, A. V. Voznesensky, and T. N. Klado; vol. iv. of "Useful Ores," including: "Silver, Lead and Zinc," by K. I. Bogdanovich, "Gold," by K. I. Bogdanovich, "Vanadium," by K. I. Bogdanovich and K. A. Nenadkevich; "Sulphuric Pyrite," by J. B. Samoiloff; "Russian Coals," with an introduction by P. I. Stepanoff—a co-operative work of 30 specialists of the different coal regions of Russia; "Naphtha and Ozokerite," by D. B. Goloubjatnikoff; "Phosphates," by J. B. Samoiloff and A. D. Arhangelsky; "Felspar," by A. E. Fersman; "Ores of Aluminium," by K. K. fon Foht; "Selenium," by F. B. Bragalia; vol. vi. of "The Animal Kingdom": "Mammals and Birds," by A. A. Silantieff and E. K. Souvorov; "Fishes," by V. I. Meisner, N. M. Knipovich, V. K. Soldatoff, I. N. Arnold, I. D. Kouznezoff, A. I. Golovkin, and A. J. Nedoshivin; "Cattle," by S. A. Ivanoff; "Poultry," by M. I. Diakoff.

(4) Reports on the Activities of the Committee: Minutes xxvii.-xxxiii., reports on 1918 and also reports from 1915 to 1920; and

(5) News from the different scientific institutions attached to the Committee: Institute for the Study of Platinum and other Rare Metals, Institute of Physico-Chemical Analysis.

All the above-mentioned bulky and valuable material in connexion with the natural resources of Russia has been published since 1918–1920. With exceptional feeling and respect one turns over these pages, written by Russian men of science, with a great love of their country, and in circumstances of the greatest privations. These privations affected not only their personal well-being, but also such things as the possibility of getting necessary scientific literature and reagents, and even the temperature of the laboratories. We can get an idea of the hardships they endure by occasional phrases we sometimes meet in their works. We learn, for example, that the temperature of the laboratory of the Polytechnical Institute in Petrograd was the same as that of the street, because the laboratory could not be heated; that the photographic section of the expedition for exploring the Karabougai Gulf could only make negatives because they had no suitable printing paper and equipment to be able to make use of silver bromide paper, etc. In spite of, or perhaps even because of these awful surroundings, Russian men of science have devoted themselves with praiseworthy neglect of self to their scientific work.

"In the dark and even perhaps seemingly hopeless days of Russian everyday life, I have tried," says

Prof. Fersman in the introduction to his book on "The Precious Stones of Russia," "to fly away into the world of the beautiful stone. I want to carry away my friends and the friends of stones from the heartrending surroundings of their everyday life, into another world, and in a number of talks I have tried to show the riches of Russia in her precious stones."

At the head of this Committee there stands a Council of the most prominent men of science. The president of the Council is a member of the Academy —Prof. V. I. Vernadsky—while another member is N. S. Kournakoff, vice-president. The Committee was founded by the Russian Academy of Science in 1915. As Russia during the War was cut off from the world's market, it had to make use of its own resources, and increased knowledge of these natural resources became necessary.

M. Vernadsky expressed this idea in the following words in 1915: "We are in such a position as regards a whole number of our natural products, that we even do not know if we have them, and if we have got them, then in what quantities—all this is because we have got used to getting them from abroad and have given up looking for them in our own country." Russia, therefore, needed a systematic survey of its natural resources in order to become self-supporting. The problem of developing the natural resources has been put forward by the Committee ever since as a great national goal.

The author of the project of founding a special institute for the geographical study of Russia, A. A. Gavriloff, says in May 1919, "The world's economy must pass through an epoch of highly organised national economies, in which the highest possible organisation of production and useful development of the natural resources of the country reduce to a minimum the competition between the different undertakings within the country. In this way is obtained increased economic strength and means for productive competition with other nations. It is only natural that Russia must needs follow along this path."

The Committee of the Academy of Science has rendered a great service to Russia by collecting and systematising so much material in connexion with the natural resources of Russia. Since 1915 to 1920 it has published 13,469 pages of scientific works. This Committee has likewise rendered a service to world economy; every foreigner who wants to take to Russia his capital or his knowledge for the development of Russia's natural resources will find in these works clear and definite answers to the questions which interest him in connexion with different branches of industry.

Limitations of space forbid a detailed account of the works mentioned above. Special attention may be directed, however, to the brilliant work of Prof. Fersman on the precious stones of Russia, and to works with most detailed and careful information on Russian coal, naphtha, platinum, and gold. Attention may also be directed to the energetic action of the Committee in supporting new industries started in Russia before the War began, such as the production of radium and vanadium from the Tuja-Mujunski mines. Before the War this was undertaken and carried out by the Fergan Society of Rare Metals. With the nationalisation of the mines this young undertaking might otherwise have been killed.

The Committee for the Study of Russia's Natural Resources has formed a special section in connexion with rare metals and radioactive substances. This includes such prominent men of science as Vernadsky and Kournakoff, both of whom are members of the Academy, and Profs. Jakovkin, Joffe, Veber, Sokoloff, Lialin, and Khlopin. What is even more, this section has obtained a Government grant, and has started works in connexion with the production of radium. Information relating to this interesting section of the work of the Committee will be found in the Transactions of the Committee of the Academy of Science for 1918.

The Geological History of South-Eastern Australia, with Special Reference to the Carboniferous and Permian Periods.[1]

By C. A. SUSSMILCH.

ROCKS of definite Archæozoic age occur only over a limited area in the western part of south-eastern Australia; they contain the important silver-lead-zinc ore-deposits of the Broken Hill District. Proterozoic strata are limited also to the same area; these contain glacial tillites which have usually in the past been considered Cambrian, but they are probably of pre-Cambrian age. No undoubted Cambrian strata are known to occur in New South Wales.

Ordovician strata are very extensively developed, both in New South Wales and in Victoria: they consist mainly of claystones with some fine-grained sandstones, and contain an abundant graptolite-fauna. Both Lower and Upper Ordovician strata are found in Victoria, but so far only the latter have been identified in New South Wales. Silurian strata are developed over extensive areas in New South Wales, particularly in the southern and central parts of the State, and extend also through the centre of Victoria; in addition to claystones, there is a considerable development of limestones, individual beds ranging up to 550 feet in thickness. An abundant coralline fauna is preserved in these limestones and there are also many brachiopods and hydrozoa.

[1] Substance of a lecture delivered before the Geological Society of London on May 21.

The sea appears to have retreated from the land at the close of the Silurian Period in south-eastern Australia, but renewed transgressions of limited extent took place early in the Devonian Period. The sedimentation which took place in these areas in Lower and Middle Devonian times was accompanied by very extensive deposition of lavas and tuffs, this being one of the important volcanic epochs of south-eastern Australia. Thick coralline limestones were also deposited during that age. Important crustal movements took place at the close of the Middle Devonian times, followed by an extensive transgression of the sea in New South Wales in the Upper Devonian Period, a transgression which extended from the present south-eastern coast almost to the far western boundaries of the State. In the strata deposited in this epicontinental sea an abundant brachiopod fauna is preserved, together with numerous fish-remains. Important crustal movements took place at the end of the Devonian Period, which brought about a complete withdrawal of the sea; much of south-eastern Australia has not since been beneath the sea.

Early in the Carboniferous Period a geosyncline developed in north-eastern New South Wales, and in this was first deposited a series of marine strata in

the latter part of Lower Carboniferous times. Following a withdrawal of the sea, an extensive series of terrestrial beds was deposited in this area in Middle and Upper Carboniferous times; these terrestrial strata consist mainly of conglomerates, volcanic rocks (lavas and tuffs), and glacial beds, of an aggregate thickness approaching 10,000 feet. The glacial beds are of such a thickness and volume as to imply intense and long-continued glaciation. Associated with these beds is a characteristic Rhacopteris fossil flora.

In Permian (Permo-Carboniferous) time an alternating series of marine and freshwater beds was deposited in the north-eastern part of New South Wales, and these extend far northwards into eastern Queensland. The freshwater beds contain the most productive coal-measures of Australia, and associated with the coal-seams is the characteristic Glossopteris flora. The glacial conditions of the Carboniferous Period continued also far into the Permian Period, but with apparently reduced intensity. The Permian Period closed in north-eastern New South Wales and south-eastern Queensland with pronounced orogenic movements, accompanied by granitic intrusions; but elsewhere in New South Wales and throughout Victoria and Tasmania, no earth-folding took place at that time.

In the Trias-Jura Period the whole of eastern Australia stood above the sea, and extended far east of the present shore-line. Upon this land there developed a number of large lake-basins in which several thousands of feet of freshwater strata were deposited, and in some areas productive coal-measures were formed. In the Cretaceous Period a transgression of the sea began in the north, and extended southwards over central Queensland into northern New South Wales, and well into central Australia. At the beginning of the Tertiary Period a tilting of the Australian continent on an east-and-west axis caused the Cretaceous sea to retreat northwards, and allowed of transgression taking place over considerable areas in the south, incidentally separating Tasmania from the mainland.

The close of the Tertiary Period was marked by a great epeirogenic uplift in eastern Australia, which produced the existing tablelands trending parallel to the eastern coast of Australia. The elevation of these tablelands was accompanied by extensive block-faulting. During the Pleistocene Period, limited high areas in New South Wales and Tasmania supported glaciers and ice-sheets; more recently, a subsidence of the land (or raising of sea-level) drowned the shore-line to an extent of about 200 feet, and still later an upward movement of the strand-line of some 10 to 20 feet has taken place.

The Japanese Earthquake of September 1, 1923.

SHORTLY after the Japanese earthquake of September 1, 1923, Mr. Takeo Kato, on behalf of the Imperial Earthquake Investigation Committee, made reconnaissances through the districts of violent shocks, especially those around Sagami Bay. He has published a preliminary report on this field study in the Journal of the Geological Society of Tokyo (vol. 30, No. 361), including some definite estimates of the loss of life and property. In Tokyo, though not a house escaped some damage, the number of houses that collapsed owing to the shock was comparatively small. The latest official statistics place the number of houses destroyed by fire in Tokyo at 316,087, the number of killed at 67,052, of injured at 32,583, and of missing at 38,980. The shocks were far stronger at Yokohama, and strongest of all in the districts around Sagami Bay. In six towns along and near the borders of the Bay, 84,300 houses were destroyed and 26,370 lives were lost.

From seismographic and other evidence, the epicentre of the great earthquake seems to lie in Sagami Bay, about midway between Oshima and Hiratsuka, near the mouth of the Sagami River, and probably a little nearer the latter place. In the two months following this shock, the number of after-shocks was more than 1350; there were 365 on September 1, and 289, 173, and 143 during the next three days; afterwards the normal decline in frequency was manifested. The epicentres of these after-shocks lay at different places more or less remote from the main one. A few minutes after the great earthquake sea-waves swamped the shores of Sagami Bay, from Shimoda in the Idzu peninsula to Misaki and Uraga in the Miura peninsula, and also along the southern part of the Boso peninsula. They caused much damage only at Ito, Atami, Kamakura, and a few other places, where the height of the waves ranged from 20 to 40 feet. No conspicuous sea-waves were seen in Tokyo Bay. No great fault-scarps or traces have been observed, but in the islet of Hatsu-shima, off Atami, a fissure was traced for about half a mile, with in some places a displacement of 3 feet or more, running in the direction N. 30° W. Another, rather more than a mile in length, was found near Nagasawa in the Miura peninsula. Both fissures may be regarded as minor faults of the main fault along which the great earthquake originated.

A remarkable upheaval of the ground took place, it is said, within a few minutes after this earthquake, over an area of about 2000 square miles, including the islet of Hatsu-shima, the headland of Manazuru, the northern border of Sagami Bay, the Miura and Boso peninsulas. The greatest upheaval (about 8 feet) occurred at Tomizaki, along the southern coast of the Boso peninsula, and it is remarkable that here the ground settled down more than a foot within one month after the upheaval. According to the soundings made by the Navy Hydrographic Office, conspicuous changes in depth, of 50 fathoms and more, have occurred at various places in the deepest portion of Sagami Bay. Soundings are still being carried out in the Bay, while many levelling parties of the Military Department are engaged in ascertaining the changes in elevation throughout the earthquake area.

It is worthy of notice that the epicentre lies in the deepest region of Sagami Bay. This trough, which has a N.N.W. direction from Oshima to Hiratsuka, appears to be the southern continuation of the valley of the Sagami River running in the same direction. Moreover, tectonic lines in this direction are numerous, as indicated by the coast borders, valley courses, etc., and the minor faults at Hatsu-shima and Nagasawa run nearly parallel to this direction. The origin of the earthquake is attributed to a great compressive force, probably from the east, which has been accumulating for a long time. The last great earthquake in the district occurred on November 22, 1703, and seems to have originated in a great fault along the same tectonic line, the epicentre lying apparently a little to the south of that in 1923. A similar upheaval of land is recorded at that time.

C. D.

University and Educational Intelligence.

BIRMINGHAM.—At the annual Degree Congregation held on July 5 the Chancellor (Viscount Cecil of Chelwood) conferred the honorary degree of LL.D. on His Excellency Count de St. Aulaire, The Rt. Hon. Reginald M'Kenna, Sir Charles Sherrington, Sir John Bland Sutton, Sir Arthur Keith, Sir Henry Fowler, Sir Graham Balfour, Prof. Samuel Alexander, Prof. G. H. Hardy, Prof. F. Gowland Hopkins, and Prof. P. F. Frankland.

There were 4 successful candidates for the degree of Ph.D. and 18 for M.Sc. In the Honours Schools the degree of B.Sc. was conferred on 3 in mathematics, 8 in physics, 17 in chemistry, 1 in zoology, 3 in botany, 2 in biochemistry, and 26 in engineering, mining, and metallurgy. For the ordinary degree of B.Sc., 62 candidates were presented, and for the degrees of M.B., Ch.B., 29.

Mr. A. W. Nash has been appointed professor in oil mining. Educated as a civil and mechanical engineer, Mr. Nash has had fifteen years' experience in oil mining in Persia, Burma, Egypt, Russia, Hungary, Rumania, and Poland, and for the last two years he has been lecturer in oil mining in the University.

Mr. H. Beckwith Whitehouse has been appointed professor of midwifery and diseases of women. Mr. Whitehouse was educated at Malvern College and St. Thomas's Hospital Medical School, and among other posts he has held that of Hunterian professor to the Royal College of Surgeons, England.

Dr. James Maclure Smellie has been appointed lecturer in pharmacology and therapeutics; and Mr. Bernard G. Goodwin has been appointed assistant to the chair of surgery.

Miss Mabel Geraldine Carter has been appointed temporary lecturer in biology.

Some anxiety has been shown in the local press as to the openings available for the graduates in science now leaving the University. Prof. G. T. Morgan, in a letter to the *Birmingham Post* of July 5, directs attention to the fact that graduates of the University find employment more readily in other large towns than in Birmingham itself. Prof. Morgan observes that he himself is frequently consulted by local manufacturers in search of advice in chemical problems, and he suggests that many of these inquirers would find it highly advantageous to select a chemical staff of their own from the ranks of trained chemists who are being produced yearly in the University.

CAMBRIDGE.—Dr. J. Chadwick, Gonville and Caius College, has been appointed Assistant Director of Radioactive Research at the Cavendish Laboratory. Mr. H. Thirkill, Clare College, and Dr. C. D. Ellis, Trinity College, have been appointed demonstrators in experimental physics; Mr. F. W. Dootson, Trinity Hall, Mr. H. M'Combie, King's College, Mr. W. G. Palmer, St. John's College, and Mr. A. J. Berry, Downing College, have been appointed demonstrators in chemistry. Mr. J. C. Wallace has been re-elected to a junior fellowship at Emmanuel College. H. E. Baker, Corpus Christi College, has been awarded the Wiltshire Prize. Frank Smart Prizes are awarded to R. G. Tomkins, Trinity College (botany), and to G. P. Wells, Trinity College (zoology).

LEEDS.—Headingley Wesleyan College and its extensive grounds have been acquired by the University, and at the beginning of next session will be opened as a University Hall of Residence for 120 men students.

LONDON.—At a meeting of the board of the Middlesex Hospital on July 2, it was announced that Mr. S. A. Courtauld, for many years a generous supporter of the Middlesex Hospital and its Medical School, has given 20,000*l.* to endow the University professorship of anatomy in the Medical School.

IN connexion with the London (Royal Free Hospital) School of Medicine for Women, a 1916 bursary of the annual value of 50*l.* for five years is offered to a student who has matriculated and who wishes to enter the school in October next to begin a full course of study for a medical degree. Particulars of the bursary are obtainable from the Warden and Secretary, 8 Hunter Street, W.C.1.

MR. D. B. J. WALLACE, county agricultural organiser for Devon, has been appointed principal of the East Anglian Institute of Agriculture at Chelmsford.

FOLLOWING upon the death of Prof. J. G. Longbottom, head of the Department of Mechanics, the Governors of the Royal Technical College, Glasgow, have decided to amalgamate the Departments of Mechanics and Mechanical Engineering under Dr. A. L. Mellanby, who will in future be the professor of mechanics and mechanical engineering. Dr. W. Kerr, lecturer in mechanical engineering, has been appointed associate professor in the Department. Dr. Kerr is known for his work on the "Steam Friction of Turbine Wheels" and on the "Critical Speeds of Revolving Shafts," and in collaboration with Prof. Mellanby has published numerous papers dealing with problems connected with steam turbines.

THE University of Sydney loses this year the services of Mr. H. E. Barff, its Warden and Registrar for forty-two years, who is resigning office on account of ill-health. The abnormal increase in the number of students after the War imposed a severe strain on the administrative staff of the University and on its finances. The report for 1923 shows that the number of students in attendance in that year (2755) and in each of the four preceding years was almost, if not quite, double the number in the last year before the War. Since 1920, however, the number has been decreasing. The Sydney University Union, the oldest society of its kind in Australia, and one that challenges comparison with the Oxford and Cambridge Unions, celebrates this year its jubilee.

THE report of proceedings of the Annual Conference of the Universities of Great Britain and Ireland held in May last has been published by the Universities Bureau, 50 Russell Square, W.C.1 (price 1*s.*). The subjects discussed are: Directions in which universities might profitably develop, at the present time, were funds available; the Ph.D. Degree as an encouragement to higher study and research; universities and research in relation to the development of the natural resources and industries of the Empire; interchange of university teachers and students. We have already, in our issue of May 17, given a summary account of the proceedings. The full report covers 63 pages and includes, in addition to the speeches that were delivered, an important paper embodying the substance of a speech which Sir Frederic L. Nathan intended to make on the dependence of the British Isles and the Empire generally on imports from foreign countries and the steps which should be taken to remedy this. There is also a letter from Sir Robert Robertson, Government Chemist, on the difficulty of finding suitable candidates for posts of chemist and agricultural chemist in the Government laboratories in the Colonies.

Early Science at the Royal Society.

July 6, 1663. Dr. Wilkins undertook to engage Dr. Power to make that magnetical experiment here, which he had made in the country, according to his written account sent to Dr. Croune for the society, viz., of altering the polarity of a heated and cooled iron, by repercussing the two ends, and of destroying all the magnetism thereof, by striking such an iron in the middle.

1664. Capt. Taylor related, that he had known a Frenchman, who had a secret of tempering and hardening iron so that it would not rust; adding that the steel of a gun, which he produced, had been put in salt water, and was not affected with any rust; and that the same gun had not been oiled since it had been made, viz., for three years. The artist employed a certain water, which he concealed the ingredients of, wherein he quenched the iron eight or ten times, in order to reduce it to this condition.

July 8, 1663. Dr. Charleton presented the society with the plan of the stone antiquity at Avebury, near Marlborough, in Wiltshire, suggesting that it was worth the while to dig there under a certain triangular stone, where he conceived would be found a monument of some Danish king. Col. Long and Mr. Aubrey were desired to make farther enquiry into it.

1675. Mr. Hooke shewed an experiment concerning the resistance of air to a ball moved with and without an expanded area; of which he was desired to bring in a particular account in writing.

1685. A letter of Mr. Musgrave dated at Oxford, July 4, 1685, was read, mentioning, that a great part of the university being in arms [On occasion of the Monmouth rebellion] the Philosophical Society there was broken up for some time.

July 10, 1672. The Society intending to make a recess for some time, the members were desired, that as many of them, as could conveniently, would meet on Fridays in the afternoon at Gresham-college, to discourse of philosophical matters, and prosecute experiments; among which were recommended—Such, as might determine the queries lately sent by Mr. Newton, which involve his theory of light.—Such, as might improve Mr. Newton's reflecting telescope; and particularly to see finished a four-foot telescope of that kind, already recommended to Mr. Cock.—Such observations as might confirm those of Signor Malpighi about the existence of certain tracheæ, or spiral fibres in vegetables, that contain air: as also to endeavour to the finding out of peristaltic motion, affirmed.

1679. Divers discourses were occasioned about the several ways of tanning leather.

July 11, 1666. Dr. Croune produced a letter, written by Nicholas Stens, from Rome, mentioning the emulation between Divini and Campani about optic glasses. That Campani had been mistaken in some of his observations, taking the spots adhering to the body of Jupiter for the shadows of his satellites.

1667. Mr. Hooke reported that Dr. Croune had received from Mr. Richard Townley, Mr. Gascoyne's instrument for measuring the diameter of the stars with great exactness; which instrument was afterwards shewed to the society, with the models of some others.—Mr. Hooke mentioned, that he had invented an instrument of this kind, but upon another principle which would perform the same things better, with more certainty and more ease.

July 12, 1682. A proposal was read of Mr. John Collins for the printing a book of algebra [Thomas Baker's "The Geometrical Key"]. This was well approved of after a long debate concerning it.

Societies and Academies.

LONDON.

Royal Society, June 26.—J. W. **Nicholson**: The electrification of two parallel circular discs. The paper deals with the general application of spheroidal harmonics to the problem of two bodies not belonging to the same confocal system. The special case of two circular discs is reduced to a mathematical necessity for the determination of an infinite set of coefficients in a series involving Bessel Functions of half-integral order. This in turn is reduced to an integral equation of a new type, the kernel of which is

$$K(x, y) = \frac{\sin a(x+y)}{x+y} + \frac{\sin b(x-y)}{x-y}.$$

The equation is solved exactly, and exact expressions are found for the capacity of the double-disc condenser, and for the coefficients of capacity and induction of two discs with any charges.—J. F. **Fulton**: The influence of initial tension upon the magnitude and duration of the mechanical response in skeletal muscle. When the unexcised gastrocnemius, sartorius or semitendinosis muscle of the frog is stimulated through its cut nerve under various degrees of initial passive stretch by 50 break shocks delivered at 70 per second, so long as the circulation in the muscle remains vigorous, the following features are to be observed in the successive responses: The greater the initial tension within physiological limits, (*a*) the greater is the plateau tension of the resulting tetanus; (*b*) the longer the time of ascent to the plateau; (*c*) the greater the duration of the plateau *after* cessation of the stimuli ("after-action"). It seems that the general shape of the tetanus curve is determined by the rate of migration of the H-ions of lactic acid, and that the after-action represents the time spent by the ions in migrating from the place of their origin to the contractile interfaces upon which they act. The enhanced duration of the after-action with increasing tension is believed to result from the effect of the increased internal viscosity of the muscle upon the migration rate of the ions.—J. R. H. **Coutts**, E. M. **Crowther**, B. A. **Keen**, and S. **Odén**: An automatic and continuous recording balance. (The Odén-Keen Balance.) An improved form of automatic and continuous recording balance has been devised by combining electromagnetic control with the addition of small weights. A magnet suspended from one arm is attracted by a solenoid-current which is adjusted to maintain equipoise by the automatic movement of a contact along slide wires. The position of this contact is sufficient to define the effective weight, and is recorded on a rotating drum. On reaching a fixed point the contact is brought back to its original position by the addition of a small phosphor-bronze ball to the balance pan, and the cycle of operations recommences. The records consist of a series of stepped curves and a very open scale is obtained so that the apparatus can be used with no appreciable loss of sensitivity up to the maximum load for an analytical balance. Further, the sensitivity can be very simply adjusted for recording either rapid or slow changes of weight.—R. W. **Lunt**: Chemical studies in gaseous ionisation. Pt. I.: This communication constitutes the introduction to a series. Ionisation in hydrogen is produced by the corona due to alternating electric fields of frequency $1{\cdot}5 \times 10^7$. A new analysis of the Siemens ozoniser is advanced which affords a ready determination of the voltage gradient in the gas, and of the current carried by the ions in the gas. The mean intensity of ionisation is calculated from an equation relating the conduction

current in the gas to the known motions of ions and electrons in hydrogen. Pt. II.: The interaction between hydrogen and carbon dioxide due to the ionisation produced by alternating electric fields of frequency $1{\cdot}5 \times 10^7$ has been examined under a variety of conditions. An equimolecular mixture interacts giving a water gas equilibrium, which is also attained by exposing mixtures of carbon monoxide and water vapour to the discharge. In no case has it been possible to detect the formation of formic acid or formaldehyde. The equation used in Pt. I. for the determination of the mean intensity of ionisation in hydrogen has been extended to the determination of this quantity in the above-mentioned water-gas equilibria.—D. W. **Dye**: A self-contained standard harmonic wavemeter. The wavemeter provides a series of harmonics as a result of exactly timed electrical impulses which operate on a highly selective oscillatory circuit. The impulses are provided by either of two multivibrators. One of these has an impulse frequency of 1000 cycles per second, and is controlled in frequency by a valve-maintained tuning fork. The other multivibrator has normally a fundamental frequency of 20,000 cycles per second, and is controlled by the help of the 20th harmonic of the low-frequency multivibrator. The selector circuit consists of a specially designed variable air condenser and a set of six inductance coils of small damping decrement. The six scales are direct reading in frequency, uniform, and cover the range 10 to 1200 kilocycles. Owing to the master control of the tuning fork over both multivibrators, all the frequencies available are accurate to at least one part in ten thousand, and are not dependent upon the calibration, setting, or constancy of any electrical circuit. Intermediary subsidiary harmonics are readily obtainable from the apparatus; by the aid of these, the gaps between the main harmonics can be reduced to about 2 per cent. in frequency in the worst case.—W. L. **Bragg**: The influence of atomic arrangement on refractive index. It is assumed that the atoms, which are polarised by the electric force associated with the light wave, are spherically symmetrical ions, that the elastic yield of the ion to the polarising force is defined by a coefficient λ, which is a constant for the ion concerned, and that the polarising force may be taken to be that at the atomic centre. The birefringence of calcite and aragonite, using the X-ray determinations of crystal structures, has already been explained quantitatively. That of aluminium oxide is now explained. An attempt is made to attack the reverse problem of using the refractivity data to give information about crystal or molecular structure. A comparison of refractivity in carbonates and nitrates indicates a contraction of the NO_3 group as compared with the CO_3 group, and a value for the distance between nitrogen and oxygen atomic centres is obtained.—A. V. **Hill** and H. S. **Gasser**: The dynamics of muscular contraction. In a muscular contraction carried out with various speeds of shortening, the work done is a function of the speed, decreasing as the latter increases. This was previously attributed to the viscosity of the muscle substance. It might depend, however, upon some kind of nervous adjustment carried out through a proprioceptive reflex. The experiments were repeated on an isolated muscle stimulated directly; the same dependence of work on speed of shortening occurred. This is a characteristic, therefore, of the muscle fibre. If the work decreases with increase of speed, so also must the force of contraction, and one striking result obtained is that a quick release of a muscle through 10 to 15 per cent. of its length causes an instantaneous disappearance of tension, which then redevelops along a curve similar to the initial curve of tension development. The viscosity of a muscle increases some fifteen times while the muscle is being stimulated, and it is possible on a viscous elastic model to repeat the phenomena. The fundamental mechanical response of muscle is probably a sudden instantaneous reversible colloidal change which passes off rapidly, the external mechanical response following the internal change, but lagging behind it owing to viscosity.—G. S. **Currey**: The colouring matter of the blue pansy. The anthocyanin pigment of the blue pansy "Emperor William" consists of violanin, and the blue colour of the petals is due to the fact that the pigment is present in the form of its potassium salt; it occurs to the extent of ca. 6·3 per cent. by weight of the dried petals (=1·14 per cent. of the fresh petals). The yellow sap-pigment consists of the flavonol, rutin (viola-rutin). As crude glucoside, it is present to the extent of ca. 9·68 per cent. by weight of the dried petals (=1·75 per cent. of the fresh petals), the actual amount of pure rutin being 50·4 per cent. by weight of the crude substance, *i.e.* the dried petals contain approximately 4·9 per cent. of pure rutin (=0·88 per cent. of the fresh petals).—R. **Snow**: Conduction of excitation in stem and leaf of *Mimosa pudica*.—R. **Azuma**: Thermodynamic phenomena exhibited in a shortening or lengthening muscle. When an excited muscle is released—whether doing external work or not—during the earlier phase of tension development, the heat production is increased; when released at a later phase the heat production is diminished. When an excited muscle is stretched, the converse result is obtained. This suggests that the effects are reversible and thermodynamic in origin, superimposed upon the ordinary irreversible reactions of muscular activity. These conclusions confirm and extend recent observations by Fenn.—H. **Taylor**: The ionic nature of hæmoglobin. By laking the corpuscles by freezing and thawing and suspending in them a collodion membrane which contains a dilute salt solution and is impermeable to hæmoglobin, a Donnan equilibrium is obtained after about three hours. The membrane potential difference is measured and this gives the factor relating the ionic concentrations of the laked corpuscles and those of the crystalloid solution inside the collodion membrane. From this potential difference and an analysis of the crystalloid dialysate, the concentrations of the hydrogen and chlorine ions in the laked corpuscles have been determined. The potential differences found indicate that the hæmoglobin is behaving as an anion over the range of physiological importance. The normality of the hæmoglobin ions present indicates the maximum amounts of carbon dioxide the blood can further take up as bicarbonate.—J. **Stephenson**: On the blood-glands of earth-worms of the genus Pheretima. The blood-glands of three species of Pheretima consist of numerous small spherical follicles within the hinder part of the pharyngeal mass, and on the dorsal side of the œsophagus. A fully developed follicle consists of a fibrous capsule, a cup-shaped layer of nucleated protoplasm, a loose mass of cells within the cup, and a blood-sinus on the convexity of the cup, between this and the capsule. A blood-vessel leads off from the sinus, and another from the opposite pole of the follicle. The follicle is the seat of manufacture of blood-cells and hæmoglobin. The vascular system in annelids and in the groups derived from annelids, and possibly in other groups also, has a double origin; its peripheral portion has been evolved independently of its more central and contractile portion. The analogies between the development of the vascular system in Oligochætes and Vertebrates are convergences, and imply no genetic relationship between the two phyla.—H. Muir **Evans**: Supplementary note on the poison gland of Trygon.—E. M. **Crowther** and

A. N. **Puri**: The indirect measurement of the aqueous vapour pressure of capillary systems by the freezing-point depression of benzene. The freezing-point of benzene is depressed by an amount which is strictly proportional to the aqueous vapour pressure of an insoluble material with which it is in equilibrium, provided that surface energy is not one of the factors determining the vapour pressure of this material. The method is rapid and accurate when applied to substances such as sulphuric acid-water mixtures and certain salt hydrates. With capillary systems such as soil, the equilibrium is reached more slowly and the apparent vapour pressures show a systematic deviation which is the same for soils of widely different types. By assuming that a fraction of the water in such cases is held in micropores and making allowance for the effects of the changes in surface energy on the introduction of an additional liquid phase, it is possible to account for this deviation.—B. **Cavanagh**: Activity-measurement by the partition method. I. A new way of applying the partition-ratio is suggested as an indirect means of precise activity-measurement. Precise measurements are made of a partition-ratio at extremely low concentrations, and preliminary measurements, in the case of lithium chloride between amyl alcohol and water, are recorded, in which the normality, N/8000 (in the alcoholic phase), has been reached. The method consists essentially in the piecemeal preparation of a large amount of the phase to be analysed, and the concentration (for chemical estimation) of the solute therefrom, by a process of piecemeal extraction. The method depends on the possibility of calculating exactly, and applying by successive approximations, a correction for the amount of the solute evading extraction. Approximate values have been obtained, for the first time, for the activity coefficient of lithium chloride in amyl alcohol, at normalities ranging from 0·2 to 0·0001.—J. E. **Jones**: On the determination of molecular fields. Pt. I. By applying the methods of the kinetic theory to a new molecular model, a new theoretical formula for the coefficient of viscosity of a gas has been obtained. In the case of argon, the difference between theoretical and experimental values is nowhere greater than 0·6 per cent. over the whole range of the observations (−180° to 180° C.). Pt. II. The equation of state of a gas has been calculated for a molecular model consisting of repulsive and attractive fields, each according to an inverse power law. The formula for the *second viriel coefficient* thus obtained contains existing formulæ (for a monatomic gas) as special cases. The force constants of a gas are obtained from a comparison of the theoretical formula with observational material on the equation of state. In the case of argon, more than one molecular model will explain the facts.—C. J. **Smith**: An experimental study of the viscous properties of water-vapour. The viscosity of superheated water-vapour over the range of temperature 100°-260° C. has been determined. The method involves the transpiration of the superheated vapour through a capillary tube, determining the pressure at its ends and the mass of the vapour transpired. The variation of the viscosity with temperature can be represented by Sutherland's formula. The dimensions of the water molecule obtained are in accordance with previous investigations for other gaseous hydrides.—E. M. **Crowther** and J. R. H. **Coutts**: Discontinuity in the dehydration of certain salt hydrates. The changes in weight on rapidly drying certain salt hydrates have been recorded continuously by means of the Odén-Keen automatic recording balance. With thin layers of small crystals of copper sulphate pentahydrate and barium chloride dihydrate, the rate of evaporation shows a very marked minimum value at points corresponding to the composition of definite lower hydrates. An explanation of the observations is advanced on the basis of Langmuir's theory that heterogeneous reactions proceed only at the actual phase boundary. No evidence of discontinuities was found in the rehydration of anhydrous copper sulphate.—W. R. **Dean**: The elastic stability of an annular plate. A plane circular annular plate is under uniform shearing forces applied at its edges, and the problem is treated by the methods of the theory of thin shells. Plates with clamped edges in which the ratio of outer to inner radius exceeds 3·2 are discussed. With the analysis given, a certain type of uniform tensional stress can be allowed for in addition to the uniform shear.—R. C. **Johnson** and W. H. B. **Cameron**: The effect of argon on certain spectra. Investigations have been made of the effect of argon on spectra associated with carbon, oxygen, and sulphur; while in certain respects the action of argon and helium is similar, there are also profound differences. It has not been found possible to reproduce the "comet-tail" bands in high pressure argon, but the "triplet system" of carbon is isolated by both the inert gases. An effect of a similar type due to argon has been observed in connexion with sulphur dioxide. A band spectrum of the latter (obtained otherwise only with difficulty) was brought up strongly in the presence of high pressure argon.—G. R. **Goldsbrough**: On the possible ellipticity of Saturn's ring. Maxwell showed that a single circular ring of particles surrounding the planet Saturn would be in relative equilibrium, provided the mass of each particle was sufficiently small compared with the mass of Saturn. This result is extended to the case of an elliptical ring. By properly placing the particles on the ellipse, by allowing the ellipse to rotate slowly in its plane, and the particles to vibrate about their mean positions, then the elliptical ring is a possible dynamical form. For sufficiently small values of the mass of the particles, and for values of the eccentricity not too great, the elliptical ring will be "ordinarily" stable.—E. C. **Titchmarsh**: The double Fourier series of a discontinuous function. The object is to discuss the behaviour of the double Fourier series which represents a function of two variables, at a point where the function is discontinuous. Such a double series is not necessarily convergent in the general sense; but if it is summed in special ways, *e.g.* by rows or by columns, different sums may be obtained, depending on the values of the function in particular regions surrounding the point considered.

Geological Society, June 4.—Dr. J. W. Evans, president, in the chair.—H. H. **Swinnerton**: On a new catopterid fish from the Keuper of Nottingham. Excavations made at Woodthorpe, near Nottingham, passed through the lowest beds of the Keuper Waterstones, and brought to light numerous well-preserved remains of fossil fishes belonging chiefly to the genus Semionotus, together with specimens of a small fish which proved to be a new species of the genus Dictyopyge. This fish is only 4·5 cm. long, and slightly more than 1 cm. deep. In osteological characters it resembles the Eugnathidæ rather than the Palæoniscidæ. The pectoral girdle, however, has an infraclavicle, a feature which is diagnostic of the Catopteridæ. The detailed study of this new species confirms the usually accepted opinion that the Catopteridæ, although classed with the Chondrostei, approach the Protospondyli.—C. E. **Tilley**: A preliminary survey of metamorphic zones in the Southern Highlands of Scotland. A preliminary metamorphic survey of the Dalradian sediments enclosed within a tract extending from Dunkeld in Perthshire to the western side of Lower Loch Fyne (Argyllshire), and reaching from the Highland Border to the Ben Lui Schists that structurally overlie the Loch Tay Lime-

stone (16 miles across the strike), has been made. The important lines of dislocation, such as the Loch Tay Fault, the Luib Fault, the Tyndrum Fault, etc., displace not only the stratigraphical horizons, but also the metamorphic zones, and in the same direction. Where the boundaries of the zones cross areas of marked topographic relief, information should be provided by the trace of the zone surface. The Braes of Balquhidder, near Loch Earn, are thus favourably situated, and examination shows that the boundary-surface (isograd surface) of the almandine zone is there inclined at low angles to the north-west.

Optical Society, June 12.—Col. L. E. W. **van Albada:** Wide-angle ortho-stereoscopy: its optical, practical, and psychological advantages. In the methods used, the objects appear to the observer in their natural sizes and correct spatial relation to each other. These methods are based on the theories of Wheatstone and Helmholtz. The introduction of exaggerated perspective or other unnatural effects is avoided when the stereoscopic photographs are viewed through lenses which have nearly the same focal lengths as those by means of which the pictures were taken, and provided that the stereoscopic lenses are free from distortion. A new type of wide-angle finder made to the author's design gives a clear image over about 85°, with perfect definition up to the edge of the field. —R. J. **Trump:** Binocular vision and the stereoscopic sense. In the appreciation of distance, neither the convergence of the eyes, the visual focus, nor the variation of these accommodations as the eyes sweep over the field, plays any vital part. The recognition of a familiar type of perspective system is important, even to the extent of over-riding the evidence of binocular parallax, when the two come into conflict. This may be shown by reversing the mounting of stereoscopic photographs, or by preparing stereo diagrams in which the perspective is not in accord with the parallactic displacements. Parallax is uncertain, or even breaks down, when not assisted by perspective. There therefore appears to be no "mechanism" of stereoscopic vision dependent upon binocular parallax, but the perception of distance is a psychological function, involving the interpretation of all the details in the images in the two eyes, in the light of previous association and experience.—T. **Smith:** A general solution of the first order aberrational equations. The general equation by which the properties of the component parts of a compound optical system are determined is put into a new form. Solutions are obtained consisting of terms containing arbitrary constants together with any particular solution. The particular solution itself is the sum of two parts, one of which is independent of the corrections required in the complete instrument, while the other contains only the terms which express these special conditions.

CAMBRIDGE.

Philosophical Society, May 19.—Mr. C. T. Heycock, president, in the chair.—C. D. **Ellis:** The high energy groups of the magnetic radium-*C* β-ray spectrum. The magnetic β-ray spectrum of radium-*C* has been remeasured and the absolute energies of the lines found to an accuracy of 1 in 300. Some of the γ-rays giving these lines have energies so great as two million volts, but yet no evidence is found of any abnormal conversion, all the prominent lines being due to conversion in the *K*, *L*, *M*...electronic levels. This renders it possible to find the wave-lengths of the γ-rays. The results bring out the importance of considering the origin of the γ-rays.—R. H. **Fowler:** The statistical theory of dissociation and ionisation by collision, with applications to the capture and loss of electrons by α-particles. The statistics of general two- and three-body processes of interaction by collision are surveyed. In order to preserve standard equilibrium conditions, a definite relation must be satisfied between the number of two-body collisions which lead to any particular type of dissociation (or ionisation), and the number of three-body collisions which lead to recombination by a process which is the exact replica of the process of dissociation with a reversed time scale. This relation is used to study the laws of capture and loss of electrons by α-particles through the interaction of the field of an atomic core. The complete theory predicts Rutherford's V^5-law for the ratio of double-charged to single-charged α-particles, and gives the correct numerical value of this ratio if we may assume, as is reasonable, that the density of lightly bound electrons inside an atom is of the order 10^{24} per c.c.—D. R. **Hartree:** The spectra of some lithium-like and sodium-like atoms. By means of some theoretical relations between spectra of different atoms ionised to such an extent that their electron structures are the same, the position of lines of the spectra of some lithium-like and sodium-like atoms is estimated. In several cases these calculated lines can be correlated with lines observed by Millikan in the hot spark spectra of the corresponding elements. Lines of the spectra Be II, B III, C IV, and possibly N V and O VI, of lithium-like atoms, and of the spectra P V and S VI of sodium-like atoms, are so identified.—H. W. B. **Skinner:** The relative absorbing powers of the *L*-levels for radiation of varying wave-length. The experiment consisted in photographing the fluorescent *L* spectrum of an element using X-rays of varying wave-length to excite it. A change in the relative intensity of a pair of lines shows that the relative absorbing powers of the L_{I} and L_{III} levels depend on the wave-length of the absorbed radiation. This confirms a result recently obtained in a different way by H. Robinson. Hence the well-known λ^3 law of absorption of X-rays does not apply to an *individual L* level.—H. **Hartridge:** Are the overtones of musical sounds always harmonic? There are at the moment two rival theories: one holds that the voice overtones are harmonic, the other that they are not. Evidence available at the moment appears to be in favour of the latter view, not only for the human voice but also for most musical instruments when performing normally.—H. **Hartridge** and F. J. W. **Roughton:** Further developments in the technique for the measurement of the velocity of very rapid chemical reactions. Two different improvements have been effected: (*a*) to make the apparatus available for the investigation of chemical reaction of greater velocity; (*b*) to employ other methods, beside optical ones, for the determination of the stages arrived at by the reaction at different instants of time from its commencement. With regard to the former, it is now possible to make accurate measurements of mono- and bi-molecular reactions half completed in one-thousandth of a second. With regard to the latter, temperature changes in a moving fluid brought about by a chemical reaction can be ascertained by means of thermo-couples.—E. G. **Dymond:** On the measurement of critical potentials of gases. A method of measuring excitation and ionisation potentials is described in which the current-voltage curves are automatically differentiated. This increases the sharpness of the bends in the curves, and results in increased sensitiveness of measurement.—G. F. C. **Searle:** (1) An optical interference method of measuring Young's modulus for rods. A vertical steel rod is deflected by a load suspended from a horizontal arm attached to its upper end. Two horizontal metal plates are soldered to the steel rod and the lower plate carries a lens, the upper surface of which is

convex. The upper plate carries three adjusting screws against which a horizontal plane glass plate is held by springs. An opening in the upper plate allows the observer to view the Newton's rings formed between the lens and the glass plate when suitable illumination by sodium light is provided. The load and the lens are on opposite sides of the rod, and thus as the load is increased and the rod is bent by the bending moment, the distance between lens and plate is increased and the Newton's rings contract. For each ring that disappears at the centre, the distance between lens and plate increases by $\frac{1}{2}\lambda$, where λ is the wave-length employed. (2) A recording gyroscope. A vertical shaft carries a block to which is attached a horizontal axis. The axle of a cycle wheel is carried by a frame turning about this axis. When the wheel is spun and the proper precessional angular velocity is given to the vertical shaft, the plane of the wheel remains vertical. The upper part of the vertical shaft carries a smoked drum on which the record is made by two styles each operated by an electro-magnet. From the record taken can be found (1) the time of one complete revolution in precession, and (2) the number of revolutions of W about its own axis during that time.—D. H. **Black**: Some electrical properties of liquid sulphur. Films of distilled sulphur were obtained between two cones and the conductivity measured at various temperatures up to 200° C. It was found that the conductivity varied in a similar manner to the viscosity. The conductivity of liquid sulphur seems to be electrolytic in character.—T. M. **Cherry**: (1) The integrals of differential equations. (2) Poincaré's theorem on the non-existence of uniform integrals of dynamical equations.—H. W. **Richmond** and F. **Bath**: Loci having two systems of generating spaces.—R. **Hargreaves**: The quadratic form for radial acceleration, in the theory of relativity.—G. S. **Carter**: On the early development of the echinoderm egg. I—III.—D. **Keilin**: On the appearance of gas in the trachea of insects.—G. S. **Adair**: A comparison of the molecular weights of the proteins.—Miss I. A. **Hoggan**: The parasitism of *Plowrightia ribesia*.—R. C. **Woodward**: The overwintering of apple mildew *Podosphaera leucotricha*, in England.—K. G. **Emeleus**: The number of β-particles from radium-E. Using an electrical counter of the type devised by Geiger, the number of α- and β-particles from a source of radium-D, radium-E, and radium-F in equilibrium has been measured. After correction for reflection of β-particles at the source, their numbers were about equal. The β-rays from radium-D would not be recorded under the conditions of these experiments. On this assumption, the observed β-radiation was due to disintegration of radium-E, and since this was in equilibrium with the radium-F, it follows that about one β-particle is emitted per disintegrating atom of radium-E.

NO. 2855, VOL. 114]

Lord Kelvin.[1]

THE hundredth anniversary of the birth of William Thomson, Baron Kelvin of Largs, was commemorated in Glasgow and elsewhere on June 25. Although Glasgow was the scene of Lord Kelvin's life-work, he was actually born in Belfast, where his father, James Thomson, was professor of mathematics at the Royal Academical Institution. The city of Belfast is, indeed, very proud of its association with the illustrious physicist, and an impressive statue of Lord Kelvin adorns its Botanic Garden, adjoining the Queen's University.

William Thomson was eight years of age when his father became professor of mathematics at the University of Glasgow, and the family exchanged Belfast Lough for the Clyde. Letters are still preserved which show Thomson's love of navigation and its problems, and how he tackled some of them in his youth with the help of his brother James, afterwards professor of engineering in the University of Glasgow. He was always a sailor at heart, and his name is one of the very few names of physicists which are familiar to mariners throughout the world.

Lord Kelvin's connexion with the University of Glasgow, which began in 1832 and was only severed by his death on December 17, 1907, witnessed an extraordinary series of changes in the status of science in the world's universities. In Glasgow, as elsewhere at the beginning of his career, "Natural Philosophy," as Dr. David Murray says, "was purely an Arts subject and was regarded as an instrument for what Francis Bacon terms 'that improvement of the understanding which results from the cultivation of natural knowledge, and that elevation of mind which flows from the contemplation of the order of the universe,' and was on the same footing as Logic and Moral Philosophy; it was not treated as part of a scheme for the training of specialists. This was certainly Professor Thomson's view, who held that Greek, as an instrument of culture and mental discipline, was an essential part of the Arts course and that every scientific man should have a fair acquaintance with it."

Lord Kelvin never went to school. All his education up to the age of ten was given him by his father, along with his brothers and sisters. He used to say that he never met a better teacher in *anything* than his father was in *everything*. At a dinner of the University of Glasgow Club in London, Lord Kelvin once said that the average boy should be able by the age of twelve to write his own language with accuracy and some elegance.

[1] "William Thomson, Lord Kelvin, 1824–1907: an Oration delivered in the University of Glasgow at the Commemoration on June 25, 1924, of the Centenary of Lord Kelvin's birth," by Dr. Alexander Russell. Pp. 22. (Glasgow: MacLehose, Jackson and Co., 1924.) n.p. "Lord Kelvin as Professor in the Old College of Glasgow," by Dr. David Murray. Pp. iv+22+4 plates. (Glasgow: MacLehose, Jackson and Co., 1924.) n.p.

He should have a reading knowledge of French and German, and be able to translate Latin and easy Greek authors. He should then study logic, in order to apply his words sensibly.

Lord Kelvin matriculated in the University of Glasgow at the age of ten, and at fifteen he gained a University medal for an essay on the figure of the earth. He entered Peterhouse, Cambridge, at the age of seventeen, and in 1845 was declared second wrangler and in the following year Smith's Prizeman. In this year, at the early age of twenty-two, he was elected to the chair of natural philosophy at the University of Glasgow. "Those," he said, "were the palmy days of Natural Philosophy—the pre-commissional days." They were the days when lectures were preceded by prayer, when the professor would "meet his classes" for two hours on five days of the week for six months, and would devote the rest of the time to original research, in which chosen students might take part as assistants. *Lehrfreiheit* was a reality then, and the professor might teach whatever seemed to him best for forming the character and stimulating the imagination of the students. There was no thought of training for manual dexterity, inventiveness, or practical research. "Science" had not yet arisen as a faculty to be cultivated for its own sake or placed on an equality with the *artes humaniores*. Had the commercial value and utilisation of science been an object of university training in 1846, William Thomson would, in all probability, not have accepted the chair. Yet he himself was a shining example of the economic value of scientific knowledge and invention based upon it. He made innumerable inventions, and from some of them he derived considerable wealth, which the poverty of his early days enabled him fully to appreciate.

The sixteen years from 1850, when a steam tug laid the first submarine cable between Dover and Calais, to 1866, when the first permanent cable was laid between Europe and the United States, showed Lord Kelvin in a new light. He formulated and expounded the theory of cable transmission, and when he became a director of the Atlantic Telegraph Company, he did the work of the "drummer boy" in steering the company through the crises produced by the repeated failures of the cables. "What has been done," he said to the shareholders, "will be done again." The 1865 attempt was a failure, 1800 miles of cable being left at the bottom of the sea. But in the summer of 1866 not only was a new cable laid, but the old one was also recovered and completed.

While his work on cables gave Lord Kelvin his knighthood and the freedom of the city of Glasgow, it gave the electrical world the mirror galvanometer and the siphon recorder. These were followed by the electrostatic voltmeter and the electrodynamic balance. Lord Kelvin was a convinced advocate of the metric system, and his strenuous partisanship stimulated his colleague, Prof. Macquorn Rankine, to write his ballad "The Three-Foot Rule," which begins:

Some talk of millimetres, and some of kilogrammes,
And some of decilitres, to measure beer and drams;
But I'm a British workman, too old to go to school;
So by pounds I'll eat, and by quarts I'll drink, and I'll
work by my three-foot rule.

Lord Kelvin's laboratory, or "experimental room," as it was called, was an entirely new departure, and was the earliest physical laboratory in Great Britain. His manner of lecturing has been much admired and much criticised. Some say he was always above the heads of his students, and that he could not conceive their being subject to error. Sometimes he would let a student work out a problem of mathematical physics in the class, and would himself write down what the student dictated. After he had covered the whole blackboard on one occasion, the bewildered student said, "I am afraid, sir, I do not see where I am going." "Neither do I, Mr. Gillies; you may sit down," and the professor then sponged out all the ridiculous operations he had written down. He would, however, not tolerate facetious or irreverent answers, and would reprimand them severely.

On another occasion he despatched two students to the top of the College tower to take some observation with an electrometer. They reported the result, but it was of the opposite sign to what Lord Kelvin had expected. The professor was nonplussed, and advanced all sorts of theories to account for the result, only to reject them all as inadequate. Next morning he said he had spent the night trying to arrive at some explanation, but had not succeeded. On the third morning he appeared radiant. "Gentlemen, I have it now; they turned the instrument upside down." "It was the last thing that occurred to him," says Dr. Murray, "that a student in the Natural Philosophy class in the University of Glasgow could do so stupid a thing."

Kelvin has often been likened to Helmholtz, and for some time, indeed, the two had similar eminence and standing in their respective countries. Kelvin's almost universal genius left a lasting impression on his age. His estimate of the age of the earth has been vastly extended by the discovery of radioactivity, and his bold conception of the vortex atom is no longer regarded as corresponding in any way to reality, but he was one of the mightiest physicists who ever lived—"the foremost Cambridge man of science since Isaac Newton, and the most distinguished of the professors of the University of Glasgow."

Instinct and Culture in Human and Animal Societies.

Le Monde social des fourmis, comparé à celui de l'homme. By Auguste Forel. 5 vols. Pp. xiv + 192; iii + 184; vii + 227; vii + 172; vi + 174. (Librairie Kundig, Genève, 1921–23.) 10 Swiss francs each vol. A Summary by the author: "Mensch und Ameise." Pp. 70. (Rikola Verlag, Wien, 1922.)

MAN is an animal, albeit a social animal, and unless the study of man be made to rest on the firm foundations of biology, this study is doomed never to become a real science. The truth of this has been keenly felt by the early sociologists. In fact it has been almost an obsession with them, and the analogy between society and organism, taken literally and applied as a unique principle of research, has misled and wrecked most of the earlier attempts at systematic sociology. For in science, as everywhere else, work done by proxy, by borrowing or copying, does not lead very far. Though sociology should never break its contact with biological science, it must achieve its results by its own efforts, and recognise that the entirely different nature of its subject requires specific methods, poses new problems, and opens up new aims. The relations between human individuals in society can be compared to the intercellular process within the living organism only in a mystic, semi-poetical simile and not in any scientifically useful analogy. As a method of sociological research and exposition this simile is worse than useless, as has been proved by the unfailing sterility of the many attempts at developing such social systems.

Yet the fallacy is so firmly established, so alluring, that even a sociologist and field worker so exact and critical as the late Dr. Rivers, attempted in his last book ("Psychology and Politics," Kegan Paul, 1923) to give it currency once again. We read there, on p. 62, that the resemblance between the living organism and society "is something more than an analogy, and depends on the operation of some fundamental laws of development common to both organism and society." Again, the leading British anatomist and anthropologist, Sir Arthur Keith, approaching the problem from the biological point of view, writes in a passage, which, I confess, gave me a genuine pang of dismay, "the resemblance between the body physiological and the body political is more than an analogy: it is a reality" (The Rationalist Press Association Annual, 1924, p. 11). I fail to see why a *reality* should disguise itself as a *resemblance* and be perceptible only through an *analogy*. In any case, it is not superfluous to question the opinion of two such eminent thinkers and to give a demonstration, as I shall presently attempt to do, that there exists no analogy whatever between society and organism, in any scientifically useful sense of the word.

There are sociologists again who, abandoning the hopeless confusion between intercellular process and social relations, yet try to transfer certain theories from the evolution of life to that of societies. They regard anthropology and sociology as a science of social evolution and adapt such concepts as "struggle for existence," "natural selection," "adjustment to environment," to explain all facts of society. Apart from the recent, in the main very pertinent, criticism of exclusive evolutionism in anthropology (Pater W. Schmidt in Austria, Dr. Graebner in Germany, Dr. Rivers, Prof. Elliot Smith, and Mr. Perry in Great Britain) there is no doubt that the laws and principles of organic evolution do not hold good with relation to human societies, where the facts of organisation and culture introduce a new element and change the whole aspect of the process.

Recently we have witnessed another intrusion from biology into social science in the assertive and stimulating theory of the so-called herd instinct, which is supposed to be at the bottom of all social force and to explain all human institutions, laws, beliefs, fashions, and customs. This view, very popular among the amateur psychologists and sociologists of the day, will not bear a close sociological examination.

The question therefore remains: In what way should the sociologist establish his contact with biological science? In what exchange of services can the two studies derive mutual benefit? Where, on the other hand, must they draw the line of demarcation and recognise that the difference of their respective subject-matters precludes borrowing or encroachment? The answer to these questions cannot be hit upon *a priori* by a happy simile, inspired phrase, or armchair formula. It must come from careful comparative study of animal and human societies.

When therefore a pioneer biologist, and a student at first hand of human nature in several of its departments, summarises his life work on the social relations of ants, and does it with his attention directed to the comparative problems of human and animal sociology, this is an event of unusual importance for those who want to understand the biological foundations of society. The perusal of these five volumes, beautifully written and magnificently produced, with numerous plates, figures, and illustrations, fulfils the most exacting expectations of those who have learnt to admire Prof. Auguste Forel as a great entomologist, first-rate student of the human mind, and daring social reformer. It would be superfluous to recommend the work to the attention of the zoologist or biologist, and

no psychologist or philosopher will fail to find a mine of inspiration and suggestion in it. But its value for comparative sociology might perhaps not be so obvious, and it is on this point that it will be well to enlarge here.

The sociologist who, after his preliminary introduction (in vols. 1 and 2) to the ants, their anatomy, physiology, mentality, classification and distribution, follows up the fascinating description of their social life, will be at once impressed by the breach of continuity between the human and insect societies. Whereas in human groups, collective behaviour is co-ordinated by certain social forces, resting on *organisation* and supported by a scaffolding of *culture*, there is among the ants a complete absence of these two elements. Instead of this we find co-ordination by *instinct* and by *anatomical and physiological arrangement*.

If we compare the sociability of the ants with that of man, we find, as I have said, that the insects achieve their unity of action by instinctive arrangements which prompt each individual ant to respond to a specific stimulus in the same manner. Take, for example, their constructive activities. Prof. Forel gives a description of their natural implements, the specific bodily organs adapted in different species to different building aims. He describes the architecture of their nests, which, measured by the stature of the builders, would in certain cases dwarf the Pyramids by their size and crush sky-scrapers by their mass. When we follow the little insects at work, we find that the division of labour is rooted in the natural fact of polymorphism; that their tools and their tasks are prescribed to them by their anatomical structure; that any social organisation in the sense of hierarchy or compulsion is absent; that every insect is put in its place and works at its task, following an inner instinctive urge. Compare this with a group of men at work. Whether it be a savage community building a house or a canoe, or engaged in a hunting or fishing expedition, or whether we consider modern working men employed in some large industrial enterprise, we have a different picture. The division of labour is not based on fundamental anatomical differences, and the implements are not given by Nature but supplied by culture. The individual workers are not moved by instinct, but by the forces of social organisation which allows a small number of leaders to compel or lead or persuade the rest to work at a task in itself unpleasant. The anatomical equipment and instinctive endowment are supplanted by the gifts of material culture and the forces of social organisation.

If we study the family life of an ant-heap, and compare it with human marriage, family, and kinship organisation, we come to a similar conclusion. The biological chapter in the story of propagation is much longer and more complicated with the ants than with humans. By a natural division of functions, only a small part of the insect community is anatomically fit to mate and to produce offspring. With them the romance and tragedy of the nuptial flight and annihilation of the males, so vividly and fully described by Prof. Forel, is much more sharply defined by instinct and provided with greater variety of incidents than is the case with man. The further history of the progeny is still more complicated and requires practically in every species of ants a co-operation of one or more polymorphic forms which act as nurses, defenders, carriers, and feeders of the brood. Yet, in each phase of this very complicated process, we see that everything happens merely by the promptings of instinct, in satisfaction of a physiological need or natural craving specifically adapted to the process.

In the simplest forms of the most primitive human society, similar ends are brought about by entirely different means. While the anatomical and physiological difference is limited to the division of sexes, we see that the instinctive promptings to mate and take care of the progeny are in every one of their most elementary manifestations moulded, complicated, and co-ordinated by forces of tradition, organisation, and culture, of which we can perceive not even traces in the insect society. From the moment of birth, nay, from that of conception, the new human organism in the womb is the object of traditional observances: taboos, magical or religious rites, in higher societies hygienic rules and customary observances. The nursing, tending, and education of the child in human societies is also largely defined and consistently moulded by the tradition of the tribe; by its economic conditions, its legal system and its material culture. No doubt, both in sexual relations and in kinship bonds, the instinctive elements play a paramount rôle, yet in both they are invariably and powerfully modified by tradition. To this is due the fact that in no two savage tribes, in no two types of civilisation, do we find exactly the same sexual morals, marriage customs, or systems of kinship, while on the other hand we have to recognise that the underlying instincts and tendencies do not essentially differ throughout humanity.

M. Forel describes in detail the wars of ants, and with a certain zest of pessimism compares them with those of man. Here we see the same relation. As in love, so in hatred, the ants are moved by instinct and instinct alone. Every species, nay, every ant-heap, has its natural enemies—some stronger, some weaker, some belonging to the ant family, some to other animal domains. Against these the soldiers or workers will fight to death, using their natural anatomical weapons, moved one and all by the same hostile impulse, dropping naturally each into its place in the fighting-line.

How welcome would be such an army to one of those modern generals or politicians or journalists who seem to regard wholesale brutal destruction of life as the chief end of humanity! Yet human nature, bad as it is, and capable of unlimited depravation, is at least plastic, and it has to be fashioned into the negative evil, hostile attitude of hatred, even as it could be fashioned into an attitude of international tolerance, generosity, and desire for co-operation. Man has to manufacture the impulse of hatred, instinctively present in an ant-heap. In a savage tribe this is done by tradition, which, from generation to generation dictates to the tribesman who is his enemy and who is a friend. In our modern societies a shoddy mock-tradition of hatred is frequently manufactured in a week or so by the powerful, though despicable machinery of newspaper trusts, in which a leading mediocrity dictates to millions of others the basest and most negative feelings and impulses for destructive action. The weapons given by Nature to an ant-soldier, man had to create by means of civilisation —save the mark—and where in the insect army every soldier ant knows his place instinctively, man has to create his army organisation by ingeniously devised drill and subordination.

The chapters about the wars, predatory expeditions, and struggles of the insects in Prof. Forel's fourth and fifth volumes, read more excitingly than any imaginative novel or fantastic insect play. Some of the reflections of the author—notably in the small German booklet "Mensch und Ameise"—given with the vigour and enthusiasm of youth and with the wisdom and simplicity of age, afford admirable and inspiring reading.

We could similarly compare the economic activities of the ant-heap—their search for food, their "cattle," gardens, various arts and crafts—with those of man; or enlarge on the interesting problem of their means of mental communication and compare them with human language. The conclusion would be always the same. In human societies there exists a man-made system of material products, endowing the individual with the various implements, weapons, economic contrivances, each of which corresponds to some specific item in the anatomical equipment of the ants. Above all, there is the supreme human implement, language, which means thought and also community and continuity of thought. Language gives the possibility of tradition—that is, of the system of rules, ideals, moral precepts, laws, which mould, modify, and co-ordinate human instincts. In animal societies sociability is based directly on instinct: animals act in masses, for, having to live in masses, they are always moved by the same response to the same stimuli. Men act in groups because they are organised into societies—that is, their instincts have been shaped by tradition, a number of traditional motives has been inculcated into them, and they have been taught to use in co-operation the same apparatus of material culture, including language, the implement of thought. The animal, whether social or not, stands in immediate contact with the environment, its instincts being directly adapted to it. With man, culture stands between him and Nature as a secondary means of adaptation, and a secondary *milieu* at the same time.

This point of view will allow us to deal trenchantly with some of the fallacies enumerated at the outset: the society-organism simile, the herd instinct, and the wholesale borrowing by sociology of evolutional principles. Since the unity of the human group is brought about by the extremely complex process in which, through the co-operation of individuals and generations, tradition and culture and organisation are formed, sociology has to study this process, instead of comparing it to a thing so entirely different as a natural organic unity in which the cells of an organism are bound up. Again, since man, unlike the animal, does not stand in a direct immediate relation to environment, there is no use speaking about natural selection or struggle for existence, for these things do not apply to man, the only animal armoured by culture, tied with traditions, living in the artificial, secondary *milieu* of organised society.

Now, is there any specific herd instinct which would form the foundation of the sociability of an ant-heap? We have seen that life, in an insect community, follows several lines of typical, inherited behaviour, each associated with a special anatomical and physiological arrangement, each furnishing definite responses to specific features of the environment. Nutrition, propagation, search for food, various forms of aggression and defence, several types of symbiosis, all consist of a number of instincts each. But there is no special natural outfit, no physiological arrangement, not one single inherited tendency or response which would correspond to sheer sociality. Gregariousness is the general aspect of all their instincts, but certainly not one specific instinct. Prof. Forel does not show us anything or speak of anything even approaching herd instinct, nor can anything of the sort be detected by the most careful reader. If we have to discard this figment with reference to the most gregarious of animal societies, there can be still less room for it in the communities of man. "Human gregariousness" is even more removed from instinct than that of animals, and it consists essentially of the manner in which the various human instincts are moulded and co-ordinated by material culture and tradition, so as to result in the various mental uniformities which underlie organised behaviour.

We see, therefore, that even a brief summary of Prof. Forel's thorough and valuable results has enlightened us on the question of the biological foundations of society. We have seen that the distinctive features of human society are *organisation and culture*, the man-made, artificially created cohesion, and the man-made environment and equipment of the individual. Yet neither organisation nor culture is built up on the quicksand of human whim or creature imagination or contract or free will or historical accident or however we might call the "indeterminate mental." They are built on the foundations of instinct and in this the study of society stands in close relation to biology. But human instinct, unlike that of animals, is essentially plastic, and herein lies the possibility of culture. In studying how the plastic human instincts are modified in society, we learn to understand the nature of material culture, language, and tradition—the sum-total of civilisation. The further we push the study of the relation between instinct and culture, of the transformation of instinctive impulse into the social forces of beliefs, ideals, moral norms, and social sentiments, the better we learn to understand the enormous benefit derived by the sociologist from a comparative study of animal and human communities and the importance to him of a right understanding of the biological foundations of human character.

B. MALINOWSKI.

Oyster Mortality.

Ministry of Agriculture and Fisheries. Fishery Investigations. Series 2, Vol. 6, No. 3, 1923. An Account of Investigations into the Cause or Causes of the unusual Mortality among Oysters in English Oyster Beds during 1920 and 1921. Part I.: Report. By Dr. J. H. Orton (assisted in Laboratory Work by Miss Edith Worsnop. Pp. 199 + 12 plates. (London: H.M. Stationery Office, 1924.) 15*s.* net.

IN September 1920 there was a scare about the heavy mortality amongst the oysters on the layings of the Thames Estuary. This scare passed to Colchester, and to every part of the East Coast, and similar death-rates were also mentioned from the south and west. The matter was investigated by the Development Commission's Advisory Committee on Fishery Research, but so far as we can see from the Report before us, no accurate estimations were made of the deaths, either beforehand, or afterwards when it certainly would not have been too late; the Table given shows that unusual mortality was reported in the summer of 1921 in the Thames Estuary, and the only possible excuses for the lack of accurate investigation then are either that reports were not sent in at the time, or that the Development Commission refused to provide the funds for such. Oyster planters estimated the deaths in 1920 at 10 to 60 per cent. against an average of 10 to 15 per cent., but there is no indication upon what these estimates were based. As Holt in Ireland records losses from all causes of 39·6 and 54·6 per cent. on accurate figures, and Bulstrode showed that an English planter laid 241 millions in 13-years, and only picked up and sold 105 millions, we may be allowed to doubt the accuracy of the belief in this greatly increased and "abnormal" mortality, especially as no information is supplied as to deaths and the working of the layings in 1918 and 1919.

The Development Commission got to work with commendable rapidity. Drs. Orton, Brady, and Eyre, biologist, chemist, and bacteriologist, were engaged to investigate, and the first part of their Report is now published under Dr. Orton's name. The industry suggested poisoning by T.N.T. (tri-nitro-toluene), or some other poison, dumped into the sea, and the researches now described were mostly made to test this view. The examinations, analyses, and tank and other experiments were well conceived and done with the greatest care, but at the date on which the investigations commenced (Oct. 28) the mortality as indicated by hockley (hollow-sounding) oysters is stated to have been over. The work shows that it is "unreasonable" to suppose that the deaths can have been due to T.N.T. Various metals, nitrites, salts of picric acid and oil were considered one by one and eliminated. Indeed, the theory of poisoning would seem to have been almost definitely disproved, but we think that this disproof would have been stronger if there had been more investigation into the direction of the currents from the dumping areas, and if systematic inquiry had been undertaken into the mortality of other animals, especially near the dumps as laid down by the Advisory Committee on Fishery Research in their original resolution. Are there any records of heavy deaths among the slipper limpets or other molluscs, either on the oyster layings or elsewhere?

Coming to natural conditions, such as might be caused by fluctuations in weather, a comparison is made between 1912 and 1919 as two similar years, but no unusual mortality is recorded or recollected for 1912. The figures for layings and sales must surely be in the books of the chief oyster planters for the last twenty years, and would be interesting in this connexion; their publication could be of no harm from a trade point of view, as planters generally are sold out before the end of the season. The way the grounds are worked (cleaned up by dredging, harrowed, etc.) year by year would also require to be known, but the com-

plications introduced by that horrible American pest, the slipper limpet, would make figures of costs of little value. There were clearly large numbers of sea urchins and starfishes as well on the beds at Whitstable, but these are regarded as evidence of the healthy conditions of the beds, and the relative number of these most destructive animals in 1920 as compared with other years is not estimated; if 1919 was a year of poor shell growth, so far as thickness was concerned, either form might have caused a great rise in mortality in 1920. Dr. Orton especially asks for experiments as to temperature and salinity designed to cover yearly fluctuations.

The full results obtained by Dr. Eyre relating to oyster bacteria are deferred to Part II. of the Report, but interesting experiments with the filamentar Cladothrix are recorded. Weak oysters were found by Dr. Orton to have, as an almost constant symptom, peculiar muscle spindles, derived from the adductor muscle holding the shells together, individual spindles varying from 3μ to 90μ in length; they were also produced experimentally. This investigation and those on the crystalline style and on "bleeding" are largely new and will require to be read by every zoologist, to whom they will form the most valuable part of the researches.

The Report concludes by assigning no cause for the oyster mortality in 1920, the abnormality of which, as compared both with other years and the known conditions of certain of the grounds in 1919, the writer regards as unproven; in Part II. of the Report this matter should be considered. Some estimate of the months of greatest incidence of the mortality could easily have been made by the examination of the dead shells dredged up, and any correlation with the spawning season settled, this being a period of much death. We do not know enough about the food of oysters to make possible any consideration of the partial failure of their food supply at this season, this being in the writer's opinion the chief cause of death at Helford, provided that the layings are clean.

On the whole we consider that we are justified in calling this research a "panic study," and it would seem that it was really so as it was preceded by no accurate observations such as could have been made in three days off the Colne and at Whitstable. It was directly taken charge of by the Development Commissioners, and on the face of it the story as to T.N.T. and other poisons, comparing quantities dumped with the amount of water and its circulation, was a foolish scare. As an industrial matter it had to be undertaken in a special form, and certainly the excellent quality of the work put into it makes it scientifically valuable. All readers will be in agreement with Dr. Orton that we know far too little about the oyster, and that a good means of procuring knowledge would be that somebody "should found a Scholarship for Research on Oysters of a value of at least 300*l.* per annum" under suitable conditions, a suggestion that we would at once commend to the Development Commissioners. J. STANLEY GARDINER.

Three-Dimensional Geometry.

Principles of Geometry. By Prof. H. F. Baker. Vol. 3: Solid Geometry, Quadrics, Cubic Curves in Space, Cubic Surfaces. Pp. xix+228. (Cambridge: At the University Press, 1923.) 15*s.* net.

IT is an undoubted fact that greater intellectual satisfaction is to be obtained from the proof of a geometrical theorem by the methods of pure geometry than from an algebraical investigation of the same theorem, and treatises on the methods of projective geometry are not uncommon, even in English. But apparently the application of such methods to the study of three-dimensional problems is considered difficult, for English text-books either confine themselves to plane geometry or else devote a chapter at the end to a meagre account of quadrics. As for investigating by this means the properties of a space cubic curve or a cubic surface, that is never dreamt of. Salmon's "Geometry of Three Dimensions" is, we believe, the only English book which gives at all a complete account of the cubic surface, and in Salmon, of course, the algebraical side preponderates. Prof. Baker's third volume fills, then, an undoubted gap. To get into 223 pages an account of quadrics, of the space cubic and of the cubic surface, has involved a great amount of compression which is perhaps to be regretted; the book makes difficult reading, but the matter is there, and whoever will take the trouble to study its pages with care will be amply rewarded.

The method of treatment follows on the lines laid down in the previous volumes, the second of which was noticed in our issue of September 22, 1923, p. 428, though naturally less emphasis is put upon the logical point of view and algebra is used more freely in illustration of and supplementary to the geometrical work.

The first two chapters, parallel to chaps. i. and ii. of vol. 2, deal with the quadric surface defined by means of its generators and with its relations to a fixed conic, the properties of spheres, of circular sections, and of confocal quadrics coming in in their natural place. The elements of the theory of the linear complex and of the tetrahedral complex are touched upon by the way. Chap. iii. treats of the space cubic curve, arising as the further intersection of two quadrics with a common generator, or obtained as the locus of intersection of corresponding planes of three related axial pencils.

A series of examples gives in summary form many properties of the curve and its construction to satisfy various sets of conditions; for example, it is shown that two general space cubics have ten common chords and that there are six space cubics having six arbitrary lines as chords. The theory of self-polar tetrads and of self-conjugate pentads and hexads on the curve is also developed.

The final chapter is introductory to the theory of the general cubic surface, which it is intended to discuss later in connexion with a configuration in four dimensions. The well-known double-six theorem is first investigated and examples are considered of the figure of twenty-seven lines arising therefrom. A geometrical definition of the cubic surface is then given, and it is shown that there are families of space cubics lying upon it. This leads to the representation of the surface upon a plane. Other matters which are summarised in this chapter are the reduction of the equation of the cubic surface to the sum of six or five cubes, the bitangents of a plane quartic curve, the Hessian surface of a cubic surface, the four-nodal cubic surface and its dual, the Steiner quartic surface.

This book, it is safe to prophesy, will become one of the most treasured possessions of the student of geometry. F. P. W.

Our Bookshelf.

The Flora of the Malay Peninsula. By Henry N. Ridley. (Published under the Authority of the Government of the Straits Settlements and Federated Malay States.) Vol. 2: Gamopetalæ. Pp. vi+672. Vol. 3: Apetalæ. Pp. vi+406. (London: L. Reeve and Co., Ltd., 1924.) 42*s.* net each vol.

VOL. 1 of this series was noticed in NATURE of January 6, 1923, p. 6. Of Vols. 2 and 3 which have now appeared, the former deals with the Gamopetalæ from Caprifoliaceæ to Labiatæ, and the latter with the Apetalæ from Nyctagineæ to Salicineæ. The arrangement of the natural families is that of the "Genera Plantarum" except that in the second volume the Plantagineæ are inserted after the Plumbagineæ, and the Cardiopteridæ after the Convolvulaceæ. In the third volume the Aristolochiaceæ and Nepenthaceæ are transposed, the Hernandiaceæ are separated from the Laurineæ and the Opiliaceæ are included. The Urticaceæ are, however, still retained as one general family.

It is easy and perhaps somewhat ungenerous to criticise a work of the size and importance of this first complete flora of the Malay Peninsula. Moreover, it is rare that such an expert in field work as is Mr. Ridley should be equally at home in the herbarium, but it is undoubtedly due to this uncommon combination of capabilities that we find many points which are apt to provide difficulties to less fortunately equipped workers. For example, the contrasting in certain of the keys of comparative values only renders them valueless to a worker who may be in possession of one of the species only. Again, the frequent use of the abbreviation *l.c.* entails considerable search for the orginal quotation, and in the majority of cases is not a saving of space. Had the measurements been given in parts of a metre instead of tenths of an inch the work would have been more in accordance with present-day standards.

The work generally is of the nature of the old-time flora intended purely for the systematist. There must be a mass of information available which might have been indicated briefly, as for example on the ecology of the plants cited, for the very short extracts of field notes quoted are but little help to a worker who has not an intimate knowledge of the country and its vegetation. For workers in Malaya an index to the vernacular names cited would have been of great help, for in that country, where Malay is the common language, the plant names are first learnt in that language, and such an index would introduce the work to a much wider circle.

The references to the new species leave much to be desired. In the second volume there are one hundred and five and in the third volume twenty new species and new names given. The differential diagnosis is confined to a wholly inadequate line or mention in the key, and where the affinity lies with an extra-Malayan plant it is left to an occasional footnote to give assistance. Further, and what is perhaps worse in scarcely any cases are specimens quoted, only collectors' names. The figures are well drawn by Mr Hutchinson, and it is to be regretted that they are so limited in number. It is a pity there are so many minor imperfections to detract from the value of a work of first-class importance executed by an author with such a unique experience.

Differential Equations in Applied Chemistry. By Prof Frank Lauren Hitchcock and Prof. Clark Shove Robinson. Pp. vi+110. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd. 1923.) 7*s.* 6*d.* net.

THE problem of providing a student of one of the experimental sciences with a broad basis of mathematical knowledge coupled with the special technical facility in the subject required for the development of his own field is no mean one. Especially does it become acute, now that increasing demands of the teachers of his principal subject establish an ever greater monopoly of his time during training. Hence partly, the reason why so many chemistry, physics biology, and engineering students return in later years to their mathematical masters for expert assistance but this is not the whole truth. Teachers of mathematics must equally share the blame.

A reorganisation of mathematical teaching along "functional" lines is clearly indicated, and until that is undertaken seriously so that the methods are consciously directed to, and arrive at a concrete end with a detailed application to real and not "mathematician's" problems, much of our present teaching must be futile. The attitude of many teachers to their subject is false and cramped. In the introduction to this otherwise excellent book, for example we are informed that the student (of chemistry) has two important needs in mathematical technique:

(1) How to integrate the differential equation.

(2) How to perform the calculations needed to obtain an answer correct within the practical requirements of the problem.

Now this would be excellent were it not for the fact that (2) *is* (1) in practice; it is the exception to encounter an equation that can be "integrated" in the sense that it belongs to one of the so-called "Standard Forms," and recourse must then generally be had to approximations, *i.e.* to (2). But it is just the processes included in (2) that receive the least attention, and it is exactly a discussion of the "Standard Forms" that usually delimits the scope of the knowledge of differential equations acquired by physical and chemical students. The reason is not far to seek. They owe their pedagogic prominence to the position given to them in the earliest books on "Differential Equations," and retained ever since. For certain branches of "functional" teaching in mathematics little would be lost by "scrapping" the lot.

The present little book is an heroic attempt to make the best of both worlds by restricting attention only to equations that are integrable and useful.

H. LEVY.

Smithsonian Miscellaneous Collections. Vol. 74, No. 1: *Smithsonian Mathematical Formulæ and Tables of Elliptic Functions.* Mathematical Formulæ prepared by Prof. Edwin P. Adams; Tables of Elliptic Functions prepared under the Direction of Sir George Greenhill by Col. R. L. Hippisley. (Publication 2672.) Pp. viii+314. (Washington: Smithsonian Institution.)

THIS volume contains, in addition to the series of formulas of many branches of applied mathematics prepared by Prof. E. P. Adams of Princeton, a table of the elliptic functions, with an illustrated discussion of their chief applications in geometry, dynamics, and electricity.

The table of the elliptic function was prepared and calculated by Col. R. L. Hippisley; it gives, in a form suitable for immediate application, the series of functions $A(r)$, $B(r)$, $C(r)$, $D(r)$, $E(r)$, $G(r)$, $F\phi$, for every degree r of the quadrant, and every degree θ of the modular angle, where $\sin\theta=\kappa$ the modulus. These had been calculated already for the British Association, and printed, but held up for want of money.

Here A, B, C, D are the theta functions of Jacobi, but normalised to zero degree, so that with $\frac{r}{90}=\frac{u}{K}$,

$$D(r)=\frac{\Theta u}{\Theta_0},\quad A(r)=\frac{Hu}{HK},\quad B(r)=A(90-r),\quad C(r)=D(90-r),$$

giving

$$\sqrt{\kappa'}\,\mathrm{sn}u=\frac{A(r)}{D(r)},\quad \mathrm{cn}u=\frac{B(r)}{D(r)},\quad \frac{\mathrm{dn}u}{\sqrt{\kappa'}}=\frac{C(r)}{D(r)}.$$

Also $\phi=\mathrm{am}u$ is the inverse function of $u=F\phi$ of Legendre; and his elliptic integral of the second kind $E\phi=\frac{rE}{90}+E(r)$, so that $E(r)=Zu$, or $\mathrm{zn}u$ of Jacobi.

Provided with these functions, the third elliptic integral Π can be expressed in a form that can be calculated numerically from the table, where the results are given to ten decimals.

Acoustics of Buildings: including Acoustics of Auditoriums and Sound-proofing of Rooms. By Prof. F. R. Watson. Pp. viii+155. (New York: J. Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1923.) 15*s.* net.

THE acoustics of buildings is a subject which has always possessed importance, but with the increasing size of public buildings and the congestion of our urban populations, it has assumed much greater importance in recent decades. Though a good deal has been written on this subject, there are few books which present the problems to be solved in a lay form suitable for those not possessed of scientific attainments. Prof. Watson has succeeded in producing a volume which should prove of great value to architects concerned with the design or acoustic improvement of auditoriums, and has incorporated a number of his own researches. The volume is divided into three parts, a short introductory chapter on the principles of sound transmission scarcely deserving of a main separation, the acoustics of auditoriums, and the sound-proofing of buildings. In part 2, after explaining the behaviour of sound in a room, the nature and control of reverberation, the successful design of an auditorium and sound absorption are discussed, followed by a very interesting chapter on practical examples from existing buildings. Part 3 gives a number of experimental tests on materials by the author and others, followed by examples of sound-proofing rooms and buildings, and a special chapter on ventilation in reference to sound, while vibrations in buildings are shortly dealt with. The work is a successful attempt to bring the investigations of science to the aid of the artist and technician.

Practical Chemical Analysis of Blood: a Book designed as a Brief Survey of this Subject for Physicians and Laboratory Workers. By Prof. V. C. Myers. Second revised edition. Pp. 232. (London: Henry Kimpton, 1924.) 25*s.* net.

THE second edition of this book contains alterations and additions necessary to consider advances made in the subject during the last two years. An additional separate chapter gives the methods of blood analysis followed by Folin and Wu, and Benedict's new method of uric acid estimation is described. This edition also contains descriptions of the estimations of hæmoglobin, oxygen, calcium, inorganic phosphates, and acetone bodies, and a chapter on quantitative micro-methods of urine analysis. Numerous references to original articles, and appendices on colorimeters and standard solutions, perfect a valuable book on a subject of rapidly growing importance.

Nouvelles Vues Faraday-Maxwelliennes. Par Charles L.-R.-E. Mengès. Pp. v+94. (Paris: Gauthier-Villars et Cie., 1924.) 10 francs.

M. MENGÈS reprints and expands some papers which have appeared in the *Comptes rendus* of the Paris Academy of Sciences, chiefly on the electro-optics of moving systems. He finds the special theory of relativity self-inconsistent and proposes in some measure to revert to the older "classical" conceptions. Nothing but a detailed and complete discussion of his views would be worth undertaking; and since it is impossible to find space for this here, we offer no opinion concerning them.

Letters to the Editor.

A Possible Explanation of the Behaviour of the Hydrogen Lines in Giant Stars.

WHILE the general behaviour of the absorption lines in stellar spectra has been well accounted for by thermodynamic theory, the Balmer series shows marked peculiarities. In spite of the very high resonance potential, these lines appear even in stars of class G, and their intensity is conspicuously affected by absolute magnitude—that is, by the density of the stellar atmosphere.

According to the elementary theory, the fraction of all the hydrogen atoms present which are in the two-quantum state (and hence ready to absorb the Balmer series) should be $f_2 = q_2 e^{-(\chi_1 - \chi_2)/kT}$, where k is Boltzmann's constant, $\chi_1 - \chi_2$ the resonance potential, and q_2 the weight of the two-quantum state[1]; and this fraction should be independent of the pressure. Introducing $\chi_1 - \chi_2 = 10{\cdot}16$ volts we find $f_2 = q_2 e^{-117000/T}$. For T = 5000° (roughly corresponding to the outer atmosphere of the sun), $f_2 = 6 \times 10^{-11} \cdot q_2$; for T = 3000° (rather high for the corresponding region in an M-star), $f_2 = 8 \times 10^{-18} \cdot q_2$; and even for T = 10,000°, $f_2 = 8 \times 10^{-6} \cdot q_2$.

For comparison, we may take λ4481 of Mg+, for which $\chi_1 - \chi_2 = 8{\cdot}85$, and $f_2 = 1{\cdot}2 \times 10^{-9} \cdot q_2$ if T = 5000°. Allowance for the fact that much of the magnesium in the sun is neutral may at most reduce f_2 to $10^{-10} \cdot q_2$ of all the Mg atoms present. Now λ4481 and H_α are the strongest lines absorbed by atoms in the corresponding states; yet the former is barely visible in the solar spectrum, and the latter is one of the strongest lines of all. This would demand an absurdly great abundance of hydrogen relative to magnesium (itself an abundant element) if the effective values of q_2 were comparable. Moreover, in giant stars, and especially in super-giants, such as α Orionis and the Cepheid variables, the Balmer lines are very much stronger than in dwarf stars of the same general spectral class, though the temperatures of the latter are higher.

It appears necessary, therefore, to assume that the effective value of q_2 for the two-quantum state of hydrogen is increased, in some special way, by a very large factor, which increases as the pressure diminishes.

A tentative explanation may be found in the fact that one of the two two-quantum states of hydrogen is metastable. The state called 2_2 by Bohr (or $2p$ in the ordinary series notation) can pass to the normal $1_1(1s)$ state by emission of the resonance line λ1216; but an atom in the $2_1(2s)$ state can (so far as we know) get out of it only by the absorption of radiation, or else by a collision of the second kind with another atom or an electron. A similar condition is found in helium, where the 1σ state (the lowest in the doublet system) is metastable. There is direct evidence[2] that a helium atom may remain in this state for an average life of the order of 10^{-3} sec. or more, as against about 10^{-8} sec. for an excited atom which can get rid of its energy by radiation. The 2δ state for Mg+, concerned in the absorption of λ4481, is of the latter type.

If it may be assumed that the number of hydrogen atoms in the $2s$ state in a star's atmosphere, and hence the effective value of q_2, is greatly increased when the life of the metastable state is long, the peculiar behaviour of the Balmer lines becomes explicable. The increase in the concentration of absorbing atoms accounts for the strength of the lines; while collisions, which get the atoms back to normal and diminish this concentration, will be more frequent in the denser atmospheres of dwarf stars.

The average interval between collisions, in a gas of pressure p mm. and temperature T° K, between an atom of molecular weight m and radius r cm. and atoms of molecular weight m' and radius r' is

$$\frac{2{\cdot}24 \times 10^{-24}}{p(r+r')^2} \sqrt{\frac{mm'T}{m+m'}}.$$

For excited hydrogen atoms (for which $r = 2 \times 10^{-8}$ cm., $m = 1$) moving in a gas of temperature 5000° and pressure 0·1 mm. (roughly the conditions in the sun's reversing layer) the collision-interval comes out $1{\cdot}8 \times 10^{-4}$ sec. if the "other atoms" are ordinary hydrogen ($m = 1$, $r = 5 \times 10^{-9}$), and 9×10^{-6} sec. if they are electrons ($m = 1/1850$, $r = 0$). In a giant star, where the pressure is probably from ten to a hundred times less, these intervals would be correspondingly increased. They are evidently quite of the right order of magnitude to be dominant in determining the mean effective life of a metastable state such as has been observed in helium, and without influence on ordinary states.

The influence here suggested will be important only for atoms in metastable states of high energy content, which are more likely to lose energy than to gain it, even in collisions with other excited atoms.

We might therefore expect to find it for the familiar lines of helium. Here $\chi_1 = 24{\cdot}5$ and $\chi_2 = 4{\cdot}7$ for the 1σ state, so that f_2 should be $10^{-10} \cdot q_2$ at 10,000° and $2 \times 10^{-7} \cdot q_2$ at 15,000° (which is probably near the temperature at which the helium lines reach their greatest intensity). For λ4481, at 10,000°, $f_2 = 2{\cdot}8 \times 10^{-5} \cdot q_2$. Here again the helium lines are stronger than might be expected from the probable abundance of the element (though the latter is hard to guess at). More definite evidence is found in super-giant stars like α Cygni, where the helium lines are present, though there is no trace of them in ordinary giants of Class A_2 or even A_0.

For the Pickering series of He+, $\chi_1 = 54{\cdot}2$, $\chi_2 = 3{\cdot}4$ and $f_2 = 6 \times 10^{-9} \cdot q_2$ even at 30,000°, so that the argument from abundance would appear to be applicable.

The red triplet of oxygen, λ7772-75, for which the excitation potential is almost the same as for the Balmer series, should be strengthened in giant stars and Cepheids, and would be interesting to observe.

The great concentration of atoms in metastable states, which is here postulated, would not be expected to occur in a gas in thermodynamic equilibrium. Such concentrations have, however, often been observed experimentally in vacuum tubes, which are of course very far from being in such equilibrium. Whether the departure from equilibrium in stellar atmospheres, which undoubtedly exists, would permit a sufficient concentration to explain the observed facts in the manner here suggested may prove a problem of interest to theoretical investigators.

An observational test appears, however, to be possible. The supposed concentration affects only the $2s$ state of hydrogen, and not the $2p$ state. Of the three components of Hα, $2s - 3p$ is at 6564·516 (I.A.), $2p - 3s$ at 6564·658, and $2p - 3d$ at 6564·720. In the laboratory, the components of longer wave-length are the stronger. In the stars, that of shortest wave-length should, on our hypothesis, greatly predominate.

There is no hope of resolution of this group in the

stars, and measurement of the mean wave-length of the blend is greatly complicated by the effects of radial velocity, and of the "K term." The latter unfortunately indicates a shift in the opposite direction.

Even in the sun, radial velocity may greatly complicate the investigation. Could the $H\alpha$ line be observed double in the prominences—or show to appear single when a pair of separation 0·15 Å would certainly be resolved—the question might be settled.

Leaf-mould.

IT must be a matter of common knowledge to persons interested in woodlands that some woods and copses have a more or less thick deposit of leaf-mould, whilst in others this covering is absent. It is not a question of the presence or absence of particular trees, *e.g.* oak or beech, and it often happens that within the limits of a single wood considerable differences exist, in respect of leaf-mould formation, in different parts of it.

I have noticed that its presence or absence is very commonly correlated with the character of the surface soil. Sand or gravel promotes, whilst heavy, and especially calcareous, soils seem to inhibit its formation. In a small wood that I have had under observation for a number of years the surface varies from chalk to heavy clay, with a good deal of intermediate calcareous loam. Leaf-mould never forms naturally in this wood, although the conditions would seem to be generally favourable. The trees are reasonably thick, consisting mainly of beech and some oak. The ground is well drained and dry for the most part, whilst in other spots it is damp and even boggy. There are large hollows where leaves collect, and from which the winds never move them, even in winter. But no real leaf-mould ever forms. The mass of dead leaves and twigs rot down and evaporate, so to speak, next year. This is to be attributed to bacterial action, and I believe that for the most part the result is due to the bacteria being able to carry on the disintegration process, mainly to carbon dioxide and water, in the presence of the available calcium carbonate of the surface soil. In another wood near by there are deposits of sand and gravel overlying the loams and chalk, and there the abundance of leaf-mould is very striking.

It occurred to me that the presence of the "acid" silicious top soil might be the decisive factor in the situation. Such an acid soil, by not neutralising the products of bacterial action, would conduce to the arrest of bacterial activity and so might provide in the first-named wood the requisite condition for leaf-mould formation which had, up to that time, been lacking. This hypothesis received confirmation. A covering of sandy gravel spread over the surface of one of the hollows was followed by the formation of an excellent leaf-mould, though this had not occurred in this hollow before, nor did it take place at all in those hollows adjacent to it which had not received a coat of gravel.

I do not suppose that the whole story of leaf-mould formation is contained in the foregoing, and it may well be that in other situations additional or other factors are concerned. Indeed it seems certain that soil drainage also influences the process, perhaps through its affecting conditions of suitable aeration. At any rate it happens that when pans of clay occur near the surface of a gravel or sandy soil in woods, with the result that the ground is water-logged for a part of the year—in such places one looks in vain for leaf-mould, though a black peaty deposit may occur in its place. These peaty deposits are very different from genuine leaf-mould, though both owe their origin to the disintegration of vegetable matter.

Leaf-mould, regarded from the point of view of the succession of organisms that are concerned in its production, and of the complex chemical changes therein involved, offers an attractive field for research. It is perhaps scarcely necessary to emphasise the fact that in addition to problems of more purely scientific interest, there are others connected with it which are of industrial importance as well. The Theory of Hearing.

REFERRING to Prof. Scripture's letter in NATURE, June 28, the following observations on the vowel response of piano strings, which differ from those described, may be worth recording.

Using a small Broadwood upright piano with the lid open, and singing or speaking well into the instrument, I have found, (1) That a recognisable vowel response is given to *all* the English vowel sounds, though those to *i* (as in eat) and I (as in it) are relatively faint, owing to the poor response of the strings to frequencies of 2000 and more.

(2) That the response *is* given almost equally well, whether the vowels be intoned as prolonged or as relatively instantaneous sounds.

(3) That quite a good response is given to vowels sung "portamento" (with a variation of pitch of about an octave) or spoken as short sounds of varying laryngeal pitch. In some cases, especially in that of *u* (who), the "portamento" response is quite as good as that for the same vowel when intoned at constant pitch.

Experiment shows that a vibrating rubber strip "larynx," attached to a double resonator, will produce a constant vowel sound while the frequency of the larynx note is varied over an octave or more, by variation of the air pressure supplied to the larynx.

It seems reasonable to suppose that, in the production of a "portamento" vowel sound in the human mouth, the same thing applies—*i.e.* that the resonance frequencies of the vocal cavity remain substantially constant, though the frequency of the laryngeal puffs which evoke them is progressively changing. R. A. S. PAGET.

74 Strand, London, W.C.2.

IN reply to Prof. Scripture's letter in NATURE of June 28, I am not able to discuss the more recondite points he raises as to the nature of vowel sounds, or the mathematical formulæ by which alone, as he states, they can be subjected to analysis. I cannot, however, accept his statement that the undamped piano strings fail to respond to short spoken vowels. The facts can be tested in a moment by any one who has access to a piano. The fuller the tone of the instrument the clearer will be the response.

My own observation is that one gets a recognisable and distinguishable vowel however short the utterance, and that the quality of the resonated vowel is not noticeably changed by shortening or lengthening the vocalisation of the vowel sound; and further, that the characteristics of the vowels are as clearly distinguishable in the sharply uttered as in the sung vowel: ă, ā, i, oe, oo, all seem to come out fairly clearly and distinguishably. As Helmholtz says, the

ee is not so good. I believe this vowel contains high-pitched partials. The effect is improved by directing the voice rather more to the upper end of the sounding board so as to bring out these particular partials. The deduction that one would naturally draw from this simple experiment is that the vowels do contain musical partials, capable of being resonated so as to produce a combination of tones which is characteristic of the particular vowel employed. Of course the vowels may also contain other constituents which are incapable of being resonated, at all events by so imperfect a resonator as a piano.

The two fundamental points on which we are at issue appear to me to be these: (1) Are noises, as distinct from musical sounds, capable of being analysed by a series of resonators? (2) Are sounds of rapidly changing pitch capable of such analysis? In answering the first of these propositions in the negative, is not Prof. Scripture assuming that the limitations of analysis by Fourier's theorem and of analysis by resonators are the same? Fourier's theorem is by definition restricted to the case of recurring wave forms, *i.e.* (so far as concerns the present discussion) musical sounds, and to their analysis into fundamentals and harmonic partials. But is not this restriction imposed upon mathematicians by reason of the fact that the permutations and combinations possible when inharmonic partials are admitted are practically infinite, and consequently defy mathematical analysis? May not all sound waves be looked upon as being compounded of simple harmonic vibrations and consequently theoretically capable of analysis into their constituents? If it be admitted for the moment that the fibres of the basilar membrane with their associated fluid columns in the cochlea do actually form a complete series of resonators, any succession of pressure changes communicated to the fluid in the cochlea will set in harmonic vibration a certain number of transverse sectors of the membrane. If the components of the exciting wave are harmonic, the sectors of the membrane set in vibration will be narrow bands definitely spaced, and the result will be the sensation of a compound musical tone. If they are inharmonic the tendency will be for the different vibrating sectors to overlap so as to form vibrating *areas* with no distinguishable maximum point, and we should then have a sensation of noise of indefinite pitch.

With regard to the possibility of the resonance of inharmonic partials, inharmonic tones sounded simultaneously on a musical instrument are capable of being analysed by resonators. How then can it be maintained that inharmonic partials from a single source are not amenable to a similar analysis?

In the case of sounds of rapidly changing pitch, the completeness with which they can be analysed will depend partly on the relation of the rate of change of pitch to the periodicity of the vibrations, and partly on the degree of damping of the resonators. To speak of "damped" and "undamped" resonators, as Prof. Scripture does, seems to be rather a loose use of terms. There are no absolutely "damped" or "undamped" resonators (so far as sound is concerned). Resonators are of all degrees of damping. The cochlea is rather heavily damped, and consequently the location of resonant response in it may be changed much more rapidly than in the case of piano strings. (The silencing of piano strings when the "dampers" are down is not damping in this sense at all).

In Dr. Hartridge's pendulum experiment (NATURE, May 17, p. 713) the vibration period of the pendulums is much longer than that of sound waves. The alteration of the length of the driving pendulum must therefore be much slower than in the case of change of pitch of a musical sound if a "jangle" is to be avoided. But in Prof. Scripture's example of the Savart's wheel, or siren, which is being speeded up, if the speeding is done very rapidly the result is a disagreeable noise, which probably results from some such irregular jangle of vibrations in the cochlea as is seen in the pendulum experiment when the rate of vibration is altered too rapidly.

Still it must be conceded that the question of degree of damping and sharpness of resonance in the cochlea is the most difficult factor in the resonance hypothesis. It is far too complicated a problem to be discussed adequately in the limits of a short letter.

GEORGE WILKINSON.

Sheffield.

Specular Reflection of X-rays.

LORENZ has developed the approximate expression for the index of refraction of X-rays

$$\mu = 1 - \frac{ne^2}{2\pi m\nu^2},$$

where "n" is the number of electrons per unit volume and "e" and "m" refer to the charge and mass of the electron. This expression would indicate that at very small angles X-rays should be totally reflected by the refracting medium. The critical glancing angle is given by the formula

$$\sin\theta = \sqrt{2(1-\mu)}.$$

A. H. Compton in the June 1923 issue of the *Philosophical Magazine* shows that he finds this reflection and that it is truly total reflection. His work was done by the ionisation chamber method.

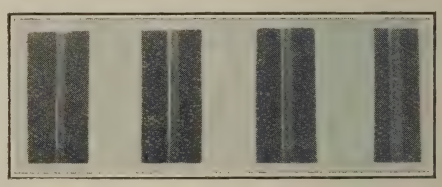

FIG. 1.

I have repeated his experiment by the photographic method, reflecting the general radiation of a molybdenum tube from crown glass. The arrangement of the apparatus differed somewhat from his. The radiation passed through a slit about 0·5 mm. wide and fell upon the surface of the glass, which was mounted on a spectrometer table. In order to obtain a sufficiently narrow beam of X-rays, the width of the beam was limited by mounting a piece of lead on the spectrometer table and pushing it as close to the glass as was necessary. The zero position of the glass was located by trial, it being taken as the position in which the primary beam was most intense. The photographic film and the slit were both 31 cm. from the centre of the glass. The angle through which the reflecting surface was rotated was measured on the spectrometer table. Angular separation on the film was twice the angle of rotation. The exposures for the reflected beam were ten minutes.

Reflection was obtained at the angles 6′, 8′, 10′, 12′. The intensity at the first three was approximately equal; at 12′ it was much less (Fig. 1). The reflected beam disappeared at 14′. These results are in accord with Compton's. The intensity of the reflected beam in this work, however, is not equal to that of the primary, being less than 20 per cent. as great. This

is probably due to the fact that the energy of the radiation from a molybdenum tube is largely concentrated in wave-lengths of about 0·4 and of about 0·7 Å.U., which have a very small critical angle. It was the longer wave-lengths, those in the region of 1 Å.U. and more, that were reflected at the angles of this experiment. This difference in intensity, therefore, is not contrary to Compton's results.

Science and Labour.

IT was obviously impossible in the general article in NATURE of June 14, on the Science and Labour Conference held at Wembley last month, to devote more than a few lines to any speaker; but for this reason I have been asked by representatives of certain research associations to correct an impression which might be gathered from the summary of my remarks concerning those associations, for the initiation of which previous governments were responsible.

In justice to the scientific workers in those associations, I should be glad if I might be permitted to explain that my criticisms were levelled against the suggestion contained in the last published report of the Advisory Committee of the Privy Council on Scientific and Industrial Research, that unless more financial support were forthcoming from the manufacturers' associations, the Government could not continue them after the expiration of the original contractual period of five years.

To my mind this amounts to a confession of the failure of the *policy* of the Advisory Committee and of the failure of a great many industries to realise the importance of research. In the first place, if the policy was to succeed, the research associations should have been given a much longer period of support. Five years is a short time to devote to most important problems in research, and even when they are solved there is abundant evidence that it takes many more years for the solutions to be applied, through no fault of the research worker, and sometimes through no fault of the manufacturers.

If the idea of co-operative research for groups of manufacturers is dropped, then, however important and commercially valuable the research already done may be, the primary object has not been achieved, and in that sense the money devoted to that object has been lost. I believe, in common with the members of the Research Committee of the National Union of Scientific Workers, that research must be fostered, and the staffs who have devoted their past few years to industrial research must be protected and kept together, with or without the financial support of the manufacturers, for industry exists for the nation and not primarily for the manufacturers. I believe the policy was wrong initially and the machinery defective, but it would be disastrous if the knowledge and the experience gained by the competent research workers were not utilised for the country. A. G. CHURCH.

House of Commons.

Birds as a Geological Agent.

MR. MARTIN has directed attention in NATURE of July 5, p. 12, to the fact that birds may carry shellfish to heights considerably above sea-level, and I remember as a student being warned against a too ready assumption of elevation of the land relatively to the sea founded on the occurrence of remains of mollusca above high-water mark. But the operations of birds in the past history of the world were probably far more extensive. Their efficiency in the distribution of seeds and minute organisms over seas is now generally acknowledged, and of course we are indebted to birds for valuable deposits of guano.

It is possible, however, that they may have played an even more important part in the destruction of other forms of life. The evolution of highly predacious sea-birds in later Mesozoic times must have been fatal to many types which had been developed without provision for protection against such foes, and it seems possible that the cessation of so many groups at the close of the Cretaceous period may be attributed to this cause. The cephalopods whose careers then came to an end would appear to have passed much of their time at the surface of the sea, where they would be an easy prey. At the same time the eggs and young of many reptiles would also be exposed to attack. The chelonians may have survived because they buried their eggs, as they do still.

Prof. Bonney suggested that it was our ancestors, the small primitive mammals, that disposed of their reptile enemies in this way. It may have been, but I cannot help thinking that the Hesperornis and its comrades were better equipped for the task. The Archæopteryx and the pterodactyls were older and presumably less efficient denizens of the air.

The Atlantic Salmon in New Zealand.

AN event of importance in the history of the acclimatisation of Salmonidæ has just recently been noted in New Zealand. For nearly sixty years New Zealand and Australia have been endeavouring to acclimatise the Atlantic salmon. (It is of interest to note that the quinnat salmon from the Californian coast is now thoroughly established in the South Island of New Zealand; recently I have identified examples from the south of the North Island.)

Fisheries' inspectors and anglers have reported that for the last two or three years *Salmo salar* was to be taken in large numbers in Lake Te Anau in Otago; but no specimens had been seen by me until recently, when Wellington fishermen took an alleged quinnat salmon in Cook Strait. This fish was examined and found to agree in most essential respects, notably the disposition of the teeth, with descriptions of *Salmo salar*. The scales, however, were smaller than commonly found by European observers. An interesting question to be decided in the future is whether we have developed our own *Salmo salar novæ-zealandiæ*, or whether we have here a chance variety which readily adapts itself to the environment.

Cook Strait is equivalent in latitude to the Spanish coast or northern part of the Mediterranean. So far as is known to science, the specimen above noted is the first Atlantic salmon ever taken in the sea in the Southern Hemisphere.

Mountain Sickness.

By Prof. JOSEPH BARCROFT, F.R.S.

SCIENTIFIC men, according to no less an authority than Longstaffe, were the pioneers of mountaineering. Its vogue as a sport followed. "During the latter part of the eighteenth century, that great period of awakening interest and research into physical science, mountain ascents were encouraged and performed only by scientific men. Such men, practical observers, and expecting to be severely affected by what we consider to be only moderate diminutions in atmospheric pressure, noted even the smallest abnormal symptoms in themselves. . . . On the other hand, during the last fifty years mountaineering has become a sport and is practised by a much larger and very different class, although it is true that many men of scientific attainments are to be found among the ranks of the modern mountaineer."

The question naturally arises: why did the ascent of mountains awaken such keen interest in the scientific men of bygone days? And it is followed by another, namely: what has been the fruit of their researches? Those were the days in which almost nothing was known about the causation of disease—in fact it is difficult to realise how little was known on this subject even so recently as falls within the memory of the still middle-aged. I cannot say what may be the limits of middle age, but I know many men born in the early 'seventies who would account themselves young rather than old, and yet if we look back to, say 1872, and ask ourselves what was then known about the causation of disease, the answer is instructive enough. Since that date the whole science of bacteriology has arisen and has enlightened us as to the cause of innumerable complaints, the micro-organisms of which are known, and by analogy as to a number of others attributable to a flora as yet undiscovered. Then there are all the diseases which are caused by trypanosomes and other parasites, the life histories of which have been worked out; the hosts which transport them have been recognised, and therefore the mechanism of their causation is understood. Or, again, consider such troubles as swollen joints, which scarcely rank among the epidemics, and yet in how many cases are they caused by micro-organisms which can be recognised. In 1872 all these things were unknown, and therefore a pathological condition which could be pinned down to an evident cause was a *rara avis* among diseases.

Such was mountain sickness: by ascending you could acquire it, and, what was perhaps more remarkable, by descending you could, within limits, throw it off. Such was the interest which, as I make out, it held for scientific men.

Mountain sickness is called in the Peruvian Andes "seroche," and the fact that it is given a definite name, which appears in medical cyclopædias, coupled with the natural scepticism of the scientific inquirer, leads to the question, "Is mountain sickness a definite medical entity?" The question is the more pertinent because its manifestations differ greatly in different individuals—differ in degree and in kind. Dr. Alfred C. Redfield, in a paper read to an American society, the manuscript of which he kindly sent me, has stated the claim of "seroche" to a place among human maladies so clearly that I can do no better than quote him. "So definite," he says, "is its symptomatology, so general is its occurrence in these not unpopulous regions, that it deserves some attention as a clinical entity. Its severity is sufficient to give it, in connexion with the mining industry, a certain economic importance. While a few men were met who had never felt it, and many who had suffered but mildly, a very large number are so greatly affected as to be completely incapacitated for several days. In at least one authentic instance the 'seroche' of a normal healthy individual has been terminated by death. Each case is an individual story and up to the present no one has been able to predict who will and who will not be affected. A description of cases of two degrees of severity will serve to picture the chief features of the disorder. Making the ascent by train,[1] one lightly touched by 'seroche' experiences his first symptoms at an altitude of 10,000 feet or more. Subjectively lassitude, then headache, usually frontal, growing in severity, and perhaps nausea, are felt. One feels cold, particularly in the extremities, the pulse quickens, respiration becomes deeper and more frequent, the face is pallid, lips and nails are cyanotic. On descending from the summit to Oroya (12,000 ft.), though a marked improvement is felt one finds himself reduced to a helpless condition of weakness which renders the least muscular effort irksome and productive of shortness of breath, dizziness and palpitation. The night's sleep is restless, and on waking one feels much as he does on venturing to his feet after recovering from an acute infection. In two or three days one's strength returns, the colour improves somewhat, and all but the more severe forms of exertion may be taken without distress. The majority are less fortunate than this. During the ascent, the symptoms are qualitatively the same, but frequently more severe, and nausea gives way to vomiting. The night's sleep fails to bring relief. Severe headache, gastro-intestinal instability, and weakness continue for several days; the body temperature may be supra-normal (102° F. in the rectum) and at times one is aware of palpitation. Cyanosis is marked. After three or four days in bed relief comes, and in a week normal activity may be resumed."

There is probably more unanimity now than at any other time as to the cause of "seroche," for there can be few, if any, men of science who do not attribute it to deficiency of oxygen. At an altitude of about 14,200 feet, the barometer stands at 457 mm., and the partial pressure of oxygen in the air cells of the human lung is just about half the normal—about 50-55 mm. instead of 100–110.

During the century and a half which have elapsed since the time when, according to Longstaffe, scientific men commenced to make observations upon mountain sickness, opinion as to the cause of the complaint has vacillated a good deal. Two theories have been serious competitors to that stated above, and they have come from very different sources: one was the invention of the distinguished physiologist, Mosso;

[1] Of the Central Railway of Peru. The train leaves Callao at the sea level about 6 A.M. and reaches the summit, 15,885 feet in altitude, near the station of Ticlio, about 3 P.M. the same afternoon.

the other was due to the entrance of the sportsman into mountaineering. Let me first discuss the latter of these two theories; it is that mountain sickness is due to a combination of fatigue, cold, bad feeding, and other discomforts incident to attempts by unfit or unathletic men to climb mountains which are beyond their physical powers.

I yield to none in my esteem of the "modern mountaineer," but, with all due respect, I would submit that he is the last person whose opinion on this subject is of value, and I have no difficulty in "stating my reasons in writing." It is of the nature of all sound scientific investigation that, in seeking out the cause of any phenomenon, only one variable should be altered at a time. Of the four variables, temperature, physical exertion, diet, and oxygen pressure, the Alpine rock climber alters all simultaneously and then pronounces to which the "seroche," if felt, is to be attributed. If you wish to see mountain sickness, do not study it among trained athletes in the Alps, whose very training makes them abnormal beings, who can only attain the rather moderate altitudes on European mountains by the performance of notable feats of physical prowess combined with exposure to extreme cold and long periods spent without a normal meal. If you wish to find out whether or no "seroche" is due to oxygen want, go to some place at which the alteration in oxygen pressure can be attained by all and sundry for a sufficient time to bring on the symptoms, but without the complications to which reference has been made. Of these localities, Pike's Peak in Colorado is good, but the best is undoubtedly that to which reference has already been made, namely, the Ticlio summit on the Central Railway of Peru.

There (year in, year out), on any of the six working days of the week, you may see a train full of passengers arrive; and if you see what I saw at Ticlio station, it will be two long coaches of the Pullman type with a head extended from each window, for, as Dr. Redfield truly says, "The majority are less fortunate . . . nausea gives way to vomiting." Here is a train load of persons, Indian, half-breed, Peruvian, European, who have been transported, if going east, from the sea level in eight or nine hours with no effort to themselves. They have had hot meals on the way, for the principal occupation of the inhabitants of the town of Matucana, at an altitude of 7700 feet, appears to be that of feeding the passengers on the train. They have not been subjected to cold; Ticlio itself is not above the snow line, though about the height of the summit of Mt. Blanc, and even if it were, the train (or at least the compartment in which I was) was heated by a stove. There, and not in the Alps, you see the clean experiment; but the truth is that you may see it without going so far afield. Many laboratories contain respiration chambers of one sort or another in which the partial pressure of oxygen may be reduced either by exhaustion, as at the Consumptive Hospital at Brompton, or in Prof. Dreyer's laboratory at Oxford, or by partial replacement of the oxygen by an indifferent gas, such as may be done in the chambers used by Dr. Haldane and by his workers in the Cambridge Physiological Laboratory. In this last-named structure it has been my unhappy fate to suffer the classical symptoms of "seroche." The pressure of oxygen was decreased from day to day till it fell to that which corresponded to an altitude of 18,000 feet. After sleeping (I use the word rather euphemistically) the night in that atmosphere, I arose to make the usual analysis of the air which was my first duty each morning. I was scarcely out of bed before vomiting set in, I suffered from an intense headache, and gas analysis was a matter of great difficulty; by an effort of concentration I could read the graduations on the gas burette, but all outside the very centre of the field of vision was a blur.

The theory of Mosso that "seroche" is due to acapnia, or insufficient carbonic acid dissolved in the tissues of the body, is not seriously now held.

Taking it, therefore, as settled that mountain sickness is due to oxygen want, the question arises, "Oxygen want of what?" And the answer is, "Of the brain."

Such evidence as is at our disposal goes to show that the brain wants but little oxygen; that little, however, it wants very badly indeed. Complete deprivation of oxygen would abolish consciousness in a matter of a few seconds. An appreciable inadequacy in the supply produces the symptoms which Dr. Redfield has enumerated. These symptoms are manifested by many organs in the body, but a careful scrutiny of them shows that they are essentially not the effects of want of oxygen on the organs themselves, but they are evidence of deficient oxygen supply to the centres in the medulla oblongata which govern the activities of these organs. Let me take a single example, that of palpitation of the heart. The effects of oxygen want on the vertebrate heart when isolated and kept beating outside the body are slowing and ultimate cessation of the beat, and a lengthening of the time which elapses between the auricular and the ventricular contractions. Yet the effect of insufficient oxygen on the heart beat in the human body is just the opposite. Dr. Somerville stated in an account of the doings of the 1922 Everest Expedition, at the Royal Society of Medicine, that on the day on which he approached 27,000 altitude his pulse was about 200 "all day" (this last phrase colloquially).

Such a phenomenon may be due to lack of vagus control over the heart, or it may be due to asphyxial nervous stimulation of the suprarenals through the sympathetic system or to direct sympathetic stimulation, or to all together, but it is not the direct effect of oxygen on the heart tissue. Yet this nervous quickening of the heart may have results which are far-reaching enough. The only observations of which I know on the circulation in a case in which the heart beat at 200 were made on a student in the Cambridge Laboratory who suffered from occasional attacks of paroxysmal tachycardia. The heart in these attacks became very inefficient, only driving about half the normal quantity of blood round the body, and almost none through the skin, which therefore became very cold. Such a condition on Everest would court frost-bite in circumstances when already it is difficult enough to cope with the cold. In this last connexion it is very interesting to note, in the experience of the Everest party, the breathing of oxygen at once brought a glow of warmth to the skin.

So it is with the other symptoms; the vomiting is no doubt the effect of oxygen want, not in the alimentary

canal but in the brain; the breathlessness also is a medullary effect, but it at least has a beneficent aspect, for the greater the quantity of air passed through the lungs (other things being equal) the higher the oxygen pressure in the air-cells, and therefore the less the tendency to mountain sickness.

We may conclude with a few sentences on the subject of acclimatisation. In an article in NATURE on the return of the Cerro de Pasco Expedition nearly two years ago (vol. 110, p. 152, July 29, 1922), I have already discussed acclimatisation in some detail. So far as the observers on that expedition could judge, the factors in acclimatisation were, as had been found by previous workers, of two categories, those which tended to increase the pressure of oxygen in the arterial blood, and those which tended to increase the quantity of oxygen which each cubic centimetre of blood carried at any specified pressure. In the latter category are (1) the increase in the number of corpuscles in each cubic centimetre of blood coupled with a corresponding increase in the hæmoglobin; (2) an increase in the affinity of the hæmoglobin for oxygen, which is probably caused by a greater alkalinity of the interior of the red corpuscle.

Among the factors which tend to increase the pressure of oxygen in the alveoli of the lung, and so of the arterial blood, is the increase in the volume of air passed through the lungs. Probably the peculiar size and shape of the chest of the native inhabitants of the Peruvian Andes tends in the same direction. A native whose height is sixty-one inches has a chest of about the same size as a European of seventy inches in stature. No account of the factors concerned in acclimatisation can be complete without reference to a possible one, namely, a more copious blood supply to the medulla. Stress has already been laid upon the fact that symptoms of mountain sickness are medullary, and more accurate knowledge is desirable of the factors which govern the blood supply of this part of the brain. Since our return from Peru, however, the work of Roberts has shown that the medullary blood supply is not simply the toy of circumstances, but is under the control of the brain itself.

Insects and Flowers.

By Dr. E. J. SALISBURY.

THE more definite relationships which subsist between organism and organism, whether it be between the algal and fungal partners of the lichen complex; between the forest tree, the orchid, or the gentian and their respective mycorrhiza; or between the Planarian worm *Convoluta Roscoffensis* and the alga Carteria, all alike bring home to one the delicacy of biotic relationships and the efficiency of whatever be the *modus operandi* of the evolutionary process. The relation between entomophilous flowers and the insects through the agency of which their pollination is effected constitutes no less remarkable an example of mutual specialisation than those already cited. It is scarcely surprising that the subject has attracted the attention of a considerable number of investigators from the observational period rendered notable by the publications of Koelreuter (1761), Delpino (1867), Mueller (1883), Darwin (1876), Kerner (1876), and Knuth (1898), to the experimental period of modern times initiated by the extensive researches of Plateau (1877–1910), and so ably followed by Lubbock (1882), Frisch (1913–19), Knoll (1919–22), and the work of Clements and Long, which has prompted and is the basis of the present article.[1]

The problems involved, though they admit of approach from either the botanical or the entomological point of view, can only be appreciated adequately if the interaction and interdependence of plant and animal be constantly before the investigator's mind. On the other hand, the earlier writers often obscured important issues by too teleological an attitude, as in the assumption that nectaries had been developed as organs of attraction for insects, whereas it is probable that, as the writer suggested fifteen years ago, all nectaries, both floral and extrafloral, originated as osmotic hydathodes and have secondarily acquired biological significance in relation to pollination. Occasionally extrafloral nectaries may themselves be important sources of honey supply, as has recently been noted for the partridge pea, *Cassia chamaecrista* (*Dixie Beekeeper*, 1922).

Every one recognises that insects, and especially bees, visit flowers for either honey or pollen, and that the process of pollination is incidental thereto. That this result ensues is the outcome of two factors, namely, the efficiency of the flower and the efficiency of the insect. With respect to floral structure, it is significant that, when closely related actinomorphic and zygomorphic types are compared, the latter are usually found to exhibit a reduction in the number of stamens and not infrequently in the ovary also; a reduction that could scarcely have come about without detriment to the race, but for the increased precision of the pollination mechanism which the zygomorphic form ensures.

It is, however, too often forgotten that pollen wastage would be enormous and insect agency almost as precarious as anemophily, were it not for the habit which bees in particular exhibit, of restricting their attentions, on a given flight, to a particular species of flower. Aristotle commented on this disposition, but the evidence respecting the degree of constancy seems to be somewhat conflicting, largely perhaps owing to lack of discrimination between the behaviour of the individual and the behaviour of the species. The observations of Clements and Long, for example, showed that the bumble bee, *Bombus juxtus*, visits at least twenty-seven species of flowers belonging to as many as twenty-two genera, and including such varied and specialised types of floral mechanism as Aconitum, Monarda, Thermopsis, and Gentiana. But when attention is confined to single individuals of this same species, the apparent fickleness of behaviour is seen to be illusory. This is sufficiently shown by the examinations of the pollen loads of twenty-five individuals of *Bombus juxtus* carried out by these investigators. Of these loads, nineteen consisted of one type of pollen only, whilst the remaining six were mixed pollen. Similar examinations of thirty-one honey-bees yielded

[1] "Experimental Pollination: an Outline of the Ecology of Flowers and Insects." By F. E. Clements and F. L. Long. Pp. vii.+274, with 17 Plates. Carnegie Institution, Washington. 4.00 dollars.

twenty-eight pure loads and three mixed loads. This high degree of constancy is not, however, always maintained with respect to the collection of nectar. The male bees, which in common with the Lepidoptera visit flowers mainly for nectar, may visit a variety of flowers even in a single flight, though constancy to one species is the general rule.

Numerous experiments in which flowers were placed in competition with one another as attractions to bees seem to show that these insects are remarkably constant to particular flowers, and that this is largely a matter of habit which tends to be perpetuated and developed owing to the increased dexterity resulting from practice. Mueller (1881) believed that the behaviour of bees indicated a psychological differentiation between the sexes, the males visiting the most accessible and fragrant flowers, whilst the thrifty females visit those which give the greatest yield of honey.

Admitting then the fact of constancy (oligotropism), it remains to inquire how the bee is attracted to the flower from a distance and on what features its taxonomic discrimination depends. The extensive experiments of Plateau, in which he employed artificial flowers of extreme perfection, showed that such are usually completely ignored, even though placed amongst their natural prototypes. The conclusion seems warranted that the perception of form and texture by bees is extremely acute. Experiments performed by Allard with the flowers of the cotton plant showed that Melissodes also has considerable discrimination with respect to structural detail. The story, recorded by F. P. Bedford, of the cabbage white butterfly which followed the artificial lilies of the valley on a lady's hat down a London street is scarcely less remarkable than that of the bee which flew to a coloured botanical wall-chart! The implied compliments in such occurrences are, however, more imaginary than real and bear testimony rather to the importance of colour and conspicuity as attractive devices than to the verisimilitude of the artifacts employed.

The experiments performed by Lubbock, in which he employed glass slips bearing honey and resting on variously coloured papers, indicated not only a preference of bees for blue, but also their colour-memory. Mueller and Lovell both obtained similar results, whilst the recent comprehensive study of Frisch (*Ver. Deut. Zoo. Ges.*, 1914), in which the range of colours was supplemented by numerous shades of grey, fully confirmed Lubbock's conclusion that bees recognise colour as such, and showed further that though distinguishing nuances of colour, there is a certain confusion similar to that of human beings colour blind to red and green.

Several investigators have shown that bees can be trained to visit a certain colour and exhibit association of impressions in a marked degree. Turner's experiments (1911) with diverse colour patterns demonstrated that amongst a mixed assemblage of these, bees usually return to the pattern to which they had become habituated. It is significant that the failures which have been experienced in the training of bees were associated with attempts to train for pure red and blue-green, unpleasant odours and geometrical patterns; that is, in respect to characteristics seldom if ever encountered by the bee under natural conditions.

It would seem to be fairly well established that colour and conspicuity are important agents of attraction up to a distance of ten metres, whilst the memory of a particular form and the less powerful odours, or their associations, serve as guides over smaller ranges of distance.

When several colour varieties of a given species are grown in proximity to one another, bees appear to visit them indifferently, which shows that form-association may predominate over colour-association. But the case of Pulmonaria shows that when colour differences are important, they are as much regarded as form. Bees visit the pink flowers of this plant freely, whereas when the corolla has turned blue, at which stage the flow of nectar has practically ceased, the flowers are neglected.

Clements and Long employed natural flowers of a variety of species, which they painted with water-colours and observed 420 visits to them as against 845 visits to the unpainted flowers. When artificial flowers were used, however, the number of visits was only about 12 per cent. of those to natural flowers, and in no case was a honey-bee deceived in this way. But, whilst this attests to the delicate perception of form, the frequent inspections made of the artificial flowers show that minute differences of structure are only detected at close range.

That vision plays an important part in influencing the flight of bees is shown by the tests on the so-called "homing" instinct. These experiments, and others using isolated plants and flowers, also show the pronounced place-memory which bees possess, despite which, however, their radius of action is usually short (about a mile from the hive).

Attraction for considerable distances may evidently be effected by strongly scented flowers, but our ignorance respecting such phenomena as the "assembling" of moths sufficiently indicates how much is still to be learnt regarding long-distance perception of stimuli. An increased number of visitors was noted by Clements and Long to flowers from which all the conspicuous parts had been removed, a result which was attributed to the greater accessibility of the nectar. In this connexion, one may recall that quite inconspicuous flowers with little or no scent but containing honey are freely visited. The odour of honey itself has been suggested as the effective agent of attraction in these cases, but the addition of honey to artificial flowers has little effect in increasing the number of visitors to them. On *a priori* grounds it would seem not unlikely that the range of light and scent perception in bees should be different from our own, but there appears to be little experimental evidence to support such a view. Various attempts have been made with mutilated insects to determine the seat of sense perception, but with regard to most of these, whatever view may be held as to the humanity of their conception, there can be little doubt as to their lack of scientific value.

There are but few observations and still fewer experiments which give any indication as to the importance of competition between flowers for the visits of insects. Robertson (1914) held that the flora is the limiting factor to the size of the bee population, whereas Lovell (1914) held that bees only collect a portion of the available pollen and nectar. The latter is probably the more correct view, and cases have been recorded

from gardens of species which are normally visited being entirely neglected for more attractive types. Upon the acuteness of this competition depends the importance to be attached to the sequence of flowering periods. Clements and Long, using the method of reciprocal bouquets, came to the conclusion that habit was the most important factor in determining preference, but that abundance of nectar or ease of access might overcome the effect of custom.

The marked capacity for memorisation by bees which training experiments reveal show that features of floral construction, of an apparently trivial character, may be of real importance in facilitating recognition. Moreover, the readiness with which bees discriminate the most profitable and easily worked flowers gives added significance to the minutiæ of floral architecture.

Further progress in the study of insect behaviour in relation to flowers would appear to demand the use of marked individuals of freshly hatched insects which have not acquired the habits that so largely determine their actions when adult.

X-ray Studies on the Crystal Structure of Iron and Steel.

AT the recent meeting of the Iron and Steel Institute Messrs. A. Westgren and G. Phragmen presented a continuation of work published by them two years ago at the same Institute. The present paper deals with the crystal structure of δ iron, the crystal shape of Cementite, and the structure of Austenite. In their previous paper a series of powder photograms of α, β, γ and δ forms of iron was reproduced. At that time all attempts to get a photogram of δ iron (stable only above 1400° C.) in the pure state had failed. Its interference lines were mingled with those originating from γ iron. By improved heating arrangements it has been possible to obtain a more uniform temperature, and the new photograms are quite free from γ interferences and confirm the conclusion previously drawn, namely, that δ iron has the same lattice structure as α and β iron.

The question as to how the atoms are grouped in Cementite (Fe_3C) has even now not been solved. The powder photogram contains a very large number of lines, some of which flow into one another. As many of the interferences of this orthorhombic substance practically coincide it could not be settled definitely, without a more thorough experimental investigation, to which of the net planes the lines of the powder photogram correspond. To decide this question so-called "complete photograms" or "rotation photograms" have been taken of a Cementite crystal obtained from the blow-hole of a spiegel melt. The only developed faces (001) were finely striated parallel to [010]. The precision camera designed for this purpose was described by the authors in NATURE of January 26, p. 122. The theory of the photograms obtained has been given by Schiebold and Polanyi. A special camera was constructed for establishing the lattice dimensions and the authors showed photograms thus obtained. The edges of the elementary parallelepiped are 4·518Å, 5·069Å, and 6·736Å. This corresponds with an axial ratio of 0·671 : 0·753 : 1. Laue photograms taken parallel with the three axes have given an axial ratio in perfect accordance with the above. If it is assumed that the elementary parallelepiped contains four molecules of Fe_3C the density of Cementite must be 7·68. Values hitherto available range from 7·74 obtained by Benedicks to 7·59 by Levin and Dornhecker.

The discrepancy which has hitherto existed with regard to the crystal structure of Cohenite—the iron carbide present in meteorites—has been cleared up. Weinschenk, who first investigated this mineral, found that its composition corresponds to Fe_3C, but concluded that it probably belonged to the regular system. Goniometric measurements were afterwards carried out by Hussak on a Cohenite crystal obtained from a Brazilian meteorite. In spite of the small size of the crystal, the fact that its faces were frequently curved, and that most of them gave very poor reflections, Hussak concluded that Cohenite belonged to the regular holohedral system. Even so, some of his angles differed 2° or more from the values characteristic of the cubic crystal. The authors show powder photograms of cementite and Cohenite which are practically identical. These two substances are therefore orthorhombic.

The authors have also used their precision camera to investigate the structure of Austenites obtained in various ways, both pure and intermixed with Martensite. They conclude that carbon dissolved in γ iron has an enlarging influence on the lattice dimensions, and that the lattice parameter changes from 3·606Å in the case of Austenite containing 0·9 per cent. of carbon, to 3·629Å in the case of the saturated solution containing 1·7 per cent. The Martensite lines, however, are too cloudy and broad to enable conclusions to be drawn concerning the lattice dimensions of the α iron in quenched steels. The authors reason that if carbon atoms replace iron atoms in the γ iron lattice the dimensions should decrease with rising carbon content, since the carbon atoms are much smaller than those of iron. Since, however, the opposite is the case, it seems probable that Austenite is not formed by simple substitution, but represents an addition product with the carbon atoms in the interstices between the metal atoms.

Precision photograms of a manganese Austenitic steel, having a lattice parameter of 3·624Å, show that in all probability this is the case. The density of the steel can be calculated either on the assumption that the iron and carbon atoms replace each other in one and the same lattice, or that the mass of the carbon atoms is uniformly distributed among the metal atoms which occupy the points of the face-centred cubic lattice. In the former case the density is 7·36, in the latter 7·83. The experimental value found was 7·83. The second assumption therefore is correct, and this Austenite is not formed by simple substitution but is an addition product. The real nature of the addition of carbon atoms cannot be decided on the basis of the results so far obtained. The authors suggest that it may be a substitution of the atoms of the γ iron lattice by complexes consisting of an iron atom combined with one or more carbon atoms.

Obituary.

SIR JETHRO TEALL, F.R.S.

BY the death on July 2 of Jethro Justinian Harris Teall, one of the most noted and revered of living geologists has been lost to science. Accomplished in all branches of geology, he gained a world-wide reputation more especially as a pioneer in petrography, at a time when the study of igneous and metamorphic rocks was as yet in its infancy. Born on January 5, 1849, he was the son of Jethro Teall by his marriage with Mary, daughter of Justinian Hathaway, of Gloucestershire. On leaving school he went to St. John's College, Cambridge, and by so doing contributed to the development of the noted school of geology which was then coming into existence under Bonney's auspices. He was bracketed second in the first class of the Natural Science Tripos in 1872, and in 1874 was awarded the Sedgwick Prize for his researches on the Lower Greensand. He held a fellowship at his college from 1875 until 1879.

For a few years after taking his degree, Teall was engaged in delivering University Extension lectures, but his tastes lay rather in the direction of original research, more especially as regards the composition and origin of igneous rocks and the phenomena of metamorphism. In such studies British geologists had been outpaced by continental workers, but the balance was restored by the publication of Teall's "British Petrography," a book which was not only far in advance of its time, but was also a classic, and still remains a standard work of reference on the subject with which it deals. In the preface he alludes briefly to circumstances which threatened a tragic termination. "The work was commenced in February 1866, and completed in March 1888. One hundred and sixty-four pages and twenty plates were issued to subscribers in monthly parts. The issue then ceased, owing to the failure of the publishers, and I was compelled to take the work into my own hands in order to finish it." A discussion which took place between Teall and some of his friends in the Geological Survey, when the fate of the book lay in doubt, remains fresh in my memory. It was distasteful to press the author to dip so deeply into his own pocket as would be necessary to complete the publication, yet it was impossible to contemplate the abandoning of a work of such outstanding importance. In the end he faced the risk of loss, and I have reason to believe was eventually recouped by the sales what he had expended on publication. He had intended to include detailed petrographic descriptions of the sedimentary rocks and crystalline schists, but though some plates were included, he was unable to find space for the letterpress. Both kinds of rocks have since received much attention, but it is a matter for regret that they were not dealt with by the same master hand.

At this time it had become apparent that the whole-time services of a petrographer were required for the Geological Survey. Assistance in the identification of igneous rocks in the field required by the surveyors, and the technical descriptions of such rocks in the Memoirs, called for the services of an expert petrographer. At the same time, the care of the petrographical laboratory and the custody of the specimens collected in illustration of the field work, pointed to the necessity of that petrographer possessing businesslike habits. Sir Archibald Geikie, Director-General at the time, selected Teall for the post, as now standing in the first rank of British petrographers. The appointment was made on June 20, 1888, to the lasting benefit of the service. Though the nature of his duties necessitated attendance at the office for a large part of the year, the petrographer was able himself to take a small share in the surveying. Thus Teall was responsible for the mapping of the northern part of Raasay, an area occupied by schists and intrusive igneous rocks.

In 1901, on the retirement of Sir Archibald Geikie, Teall was appointed Director of the Geological Survey and of the Museum of Practical Geology. The institution had recently come under the consideration of a strong committee, the appointment of which had been strongly pressed for by the staff. The committee included representatives of various Government Departments and of scientific and mining interests. The recommendations made were sound and practical, and the task of giving them effect could not have been entrusted to more capable hands than those of the new Director. While the public service benefited, the time available for his own research work was unfortunately curtailed. But for his heavy administrative duties, we may suppose that "British Petrography" might have been completed on the lines originally contemplated. In 1914 Teall retired, leaving the institution as regards its work, organisation, and remuneration in a stronger position than it had ever before held. In 1901–5 he served as a member of the Royal Commission on Coal Supplies, representing geological interests with Mr. Lapworth as his colleague, until the latter resigned on account of ill health. He received a somewhat belated honour of knighthood in 1916.

Teall received honorary degrees from the Universities of Oxford, Dublin, and St. Andrews. He was elected a fellow of the Royal Society in 1890 and twice served on the Council, once as vice-president. In 1893 he was president of Section C (Geology) of the British Association, and in 1900–2 was president of the Geological Society of London. From that Society he received the Bigsby Medal in 1889, and its highest honour, the Wollaston Medal, in 1905. In 1907 he was awarded the Delesse Prize by the Paris Academy of Sciences. In presenting the Wollaston Medal, the president (Dr. Marr) addressed Teall in words which all who knew him will endorse. "You have ever placed your great store of knowledge at the disposal of other workers. How much work was thus due to you will never be known . . . but was it known, I can safely aver that it would be found to have promoted researches concerning the mineral structures of the Earth, to so great an extent as to render you doubly deserving of this medal."

A. STRAHAN.

SIR HARRY JAMES VEITCH.

FOR several decades past there has been no such outstanding figure in the horticultural world as Sir Harry Veitch, whose death on July 6, in his eighty-fifth year, we regret to record. His chief ability was his highly developed business faculty, for he could

lay no claim to scientific distinction, probably not even to a taste for science. Nevertheless, during a long and honourable career, he did more than any one to enrich our gardens with beautiful plants from foreign countries, and in that way helped on the cause of botanical science very considerably. Whilst his primary interest was to introduce to Great Britain plants valuable from the trader's point of view, he never grudged the time his collectors spent in making pure botanical collections of dried material. The collections made by his brother, John Gould Veitch, in Japan, consisting largely of cones of pines, firs, spruces, etc., helped greatly towards the elucidation of the coniferous flora of that country, just as, thirty years later, did the collections made by Wilson that of central and western China.

Sir Harry had that supreme endowment of the business man—the faculty of finding capable assistants—and in the long roll of collectors who worked for the firm, from William Lobb in 1840 to E. H. Wilson in 1900, there are included many famous names. Scarcely less noteworthy were the activities initiated by him in the hybridisation of plants. Under his direction, the first hybrid orchid was raised, *Calanthe Dominii*, the forerunner of a branch of horticulture that has grown to enormous dimensions at the present time. Very valuable work, too, was done in the improvement of hippeastrums, the East Indian group of rhododendrons, as well as in fruits and vegetables.

Sir Harry played a great part in the International Horticultural Exhibition of 1912, and his work for it was acknowledged by the bestowal of a knighthood on him. It is interesting to recall also that he was the last survivor of the managing committee of the previous International Exhibition of 1866. His career may be safely described as unique in horticulture in its length and activity. Two valuable standard works, the "Manual of Coniferæ" and the "Manual of Orchidaceous Plants," were published under his auspices, although the actual work was done by his assistant, A. W. Kent.

About ten years ago he retired from business and, having no one to succeed him, the Chelsea firm of Veitch came to an end, an event which can only be regarded as a calamity to British horticulture, for never had it stood higher in public estimation than during the days when gardeners, both amateur and professional, watched in sadness its famous collections of trees, shrubs, and hothouse plants being dispersed under the hammer. For the rest of his life, until within a few months of his death, Sir Harry worked actively in the interests of the Royal Horticultural Society, the astonishing success of which owes much to him, and in helping the many charities in which he was interested.

We regret to announce the following deaths:

Dr. R. Kidston, F.R.S., the distinguished palæobotanist, on July 13.

Prof. A. Marshall, emeritus professor of political economy, University of Cambridge, on July 13, aged eighty-one.

Sir Sydney Russell-Wells, member of Parliament for the University of London and vice-chancellor of the University 1919–22, on July 14, aged fifty-four.

Mr. Dean C. Worcester, first secretary of the Interior, Philippine Islands, who was largely responsible for the establishment of the Bureau of Science, the Philippine General Hospital and the College of Medicine in the islands, formerly assistant professor of zoology and curator of the museum at the University of Michigan, on May 2, aged fifty-seven.

Current Topics and Events.

Representatives of a number of educational, scientific, and commercial bodies in Great Britain and Overseas attended a conference organised by the Decimal Association at the Institution of Electrical Engineers on July 9. The main subjects discussed were the Association's proposal to divide the shilling into ten pence instead of twelve, and to alter the Imperial gallon so as to make it equal to four litres. The former proposal means a twenty per cent. increase of the value of a penny, and by it "an almost complete decimal coinage would be secured, while preserving the old names of *l. s. d.* and the three-column method of book-keeping, and incidentally a reasonable solution of the present impasse in penny postage and penny fares would be found." At present, services and commodities which could be profitably provided for slightly more than a penny are subjected to a fifty per cent. increase, whereas a penny would be sufficient if the value were increased as suggested. Mr. Harold Cox, who was a member of the Royal Commission on Decimal Coinage in 1920, said at the conference that if this proposal had been before the Commission he believed the majority of the members would have been in favour of it. The proposal to make the Imperial gallon equal to four litres instead of the present 4·54, so that the quart would become one litre and the pint half a litre, arises largely from the present confusion in the use of the designation "gallon" in commercial transactions relating to motor spirit and lubricating oils. The American gallon has a capacity twenty per cent. less than the Imperial gallon, and in South America a capacity of four litres is being called a gallon, so that a single name is being used for three different quantities. The introduction of a four-litre gallon would, of course, be an important step towards the adoption of other metric weights and measures in Great Britain. Whatever may be said in favour of the British system, it can never become an international system, and as trade develops with new countries the need for the use of a universal language of quantity by British firms must become more important every year. The conference passed resolutions urging the Government to appoint a committee to examine and report upon the proposals discussed.

In connexion with a recent paragraph concerning the therapeutic action of chlorine gas, it is of interest to observe an account in the *Sunday Express* of July 6 of the introduction as an antiseptic of a compound containing chlorine. There are two ways in which chlorine can be used therapeutically; in one method, a very dilute mixture of the gas in air is

haled; in this case the effect is confined to the spiratory tract; in the other method a solution ntaining chlorine in very dilute solution is applied rectly to the injured area as an antiseptic. It is t usual to utilise a solution of the gas itself, but me compound which is readily split up giving rise to evolution of chlorine. Solutions of hypochlorous id and hypochlorites were thus used during the ar in the method of continuous irrigation of wounds. he new substance referred to in the *Sunday Express* y Callimachi is trichlorophenylmethyliodosalicylic id. It will be observed that the basis of the compound is salicylic acid, which has itself antiseptic roperties, but is more frequently in use as an antiyretic. Combined with the chlorine group, it is robable that a compound actively germicidal may e obtained; the chlorine dissociated from it will imulate the tissues to pour out white blood cells nd lymph to destroy the bacteria, while at the same me the salicylic acid radicle itself will attack the tter directly. It may be remarked that the other dicles combined with the salicylic acid will probably hance the antiseptic value of the compound.

A RECEPTION was given at one of the conference alls of the British Empire Exhibition, Wembley, on uly 8, by the Italian delegation to the World Power onference, at which some films and slides were shown nd interesting particulars were given of Italian ower plants. Ing. G. Semenza introduced Sen. rince Ginori Conti, who gave an illustrated lecture n the production of power from natural steam, which, fter a certain amount of experimenting, is now used n a practical scale in various parts of the country. he steam issues from natural fissures, or bored wells, t pressures not exceeding 3 to 5 atmospheres, at emperatures up to 150° C. On account of this low ressure and the difficulty in condensing, owing to he presence of various gases mixed with it, the atural steam is not employed direct in the engines, ut is used to heat special boilers to produce pure team at a higher pressure. The largest plant of this ind, at Lardarello, contains three turbo-alternators, ach of 4000 H.P. Ing. Emirico Vismara then showed me films illustrating hydro-electric power development in Italy, which started in 1892 with the famous ivoli-Rome transmission, and in connexion with hich plants will shortly be complete aggregating bout a million kilowatts. Very high heads are available in the mountainous districts. The Moncenisio lant, for example, works under a head of 4200 ft., and mong the extensive schemes projected in the Trentino one for utilising a head of 6150 ft. Illustrations ere given of the combination of irrigation schemes ith electric power development and the manufacture f cyanamide artificial manures by the electric furnace. he linking up of the many water-power stations into ne vast national power network is in active progress. his will involve a connexion to Sicily across the traits of Messina, for which the relative merits of a ubmarine power cable, a tunnel, and an aerial line re being investigated. The last mentioned would equire the construction of two towers, each a thousand eet high and two miles apart, to allow for a sag of 900 ft. The films shown included some very beautiful examples of Italian scenery.

IN the year 1876 Lord Kelvin, then Sir William Thomson, took an active interest in the formation of the Loan Collection of Scientific Apparatus exhibited in the Western Galleries of the Science Museum, then part of the South Kensington Museum. He was a vice-president of the section "Physics," and at the Science Conferences held in the Western Galleries in May 1876 read two papers: "The Principles of Compass Correction" and "Electrical Measurement." Many of the original instruments of his invention which were lent by him for inclusion in the Loan Collection were allowed to remain permanently on exhibition in the Museum as gifts or loans, of great interest in the history of science. Since last autumn, when the Western Galleries were cleared to make room for the Imperial War Museum, most of these valuable objects have been stored away with 80 per cent. of the science collections previously exhibited in the Western Galleries. By utilising the main gangway of the unfinished gallery of the new Science Museum building in which, since last November, the remaining 20 per cent. of the collections have been exhibited, it has been possible to bring together these original Kelvin instruments so as to form a temporary exhibition of considerable interest in connexion with the Kelvin centenary. The following objects are included: Marine galvanometer used in the Atlantic cable expedition of 1858; iron-clad marine galvanometer used on board the *Great Eastern* in the Atlantic cable expedition of 1866; double curb transmitter; syphon recorder; various types of electrometer; original models of the tide-predicting machine; harmonic analyser for tidal computation; navigational sounding machine; binnacles; mariner's compasses.

A TEMPORARY exhibition of geophysical apparatus, etc., has been placed in the new building of the Science Museum, South Kensington, in the southern half of an unfinished gallery, the contents of which have been entirely rearranged. By arrangement between the Board of Education and the Royal Society Committee organising the Exhibition of Pure Science at the British Empire Exhibition, Wembley, it was intended that this exhibition should be placed in one of the new galleries of the Science Museum, but delayed progress towards the completion of these galleries has made it necessary to arrange the collection as above. It consists chiefly of objects selected from the permanent collections of the museum. To these have been added certain objects which, owing to the limited space available in the British Government Pavilion of the British Empire Exhibition at Wembley, cannot be shown there during the whole period of that Exhibition. The collection serves to give some idea of the history of the different sciences (meteorology, seismology, gravity, terrestrial magnetism, atmospheric electricity, geodesy) included under the general heading of geophysics, and to illustrate recent British contributions to these sciences.

ARRANGEMENTS have been made to establish at Oxford in October next the Imperial Forestry

Institute, which is intended to serve as an educational and research centre for the British Empire. It will be a University institution, with the professor of forestry as its director; but it will be under the control of a Board of Governors, with a Forestry Commissioner as chairman. The educational work of the Institute will comprise (1) post-graduate training of forest service probationers and other qualified persons, (2) training of research officers in special subjects, and (3) provision of courses for selected officers already serving. The Institute will be open to various categories of students, who must as a rule have had previous training at a university in forestry or some allied science. The normal course of study will extend over one academic year, and the subjects dealt with will cover the whole range of forestry. The main cost of the Institute will fall in the first instance on the Forestry Commission and the Colonial Governments; but it is hoped that the Dominion Governments and India will give some financial assistance. Temporary accommodation has been arranged; but larger buildings will be necessary, and the formidable task of obtaining funds for the purchase of a site and the building of the Institute remains.

SUDDEN changes of temperature were characteristic of the weather conditions which prevailed in England at the close of the second week of July. An anticyclone to the south-east of the British Islands had asserted itself and was temporarily controlling the prevailing weather. With a south and south-east wind blowing from the heated continent of Europe, high summer temperatures were experienced on Saturday, July 12, the thermometer in the shade registering 87° F. at Kensington Palace, the recording station of the Meteorological Office for London, a similar reading being registered at South Farnborough and Hunstanton, while at Nairn, in the north of Scotland, the temperature was 80°. This is the highest temperature as yet this year, although it is not uncommon for summer temperatures of 90° and above to occur occasionally in London; during the heat wave and thunderstorm in July last year the thermometer on July 11 and 13 registered 92° at Greenwich, and at the corresponding time in 1921 the shade reading was 94°, while in 1900, 1911, 1912, and 1914 the thermometer rose to 90° and above in July. The highest shade temperature on record at Greenwich is 100° on August 9, 1911. Owing to the spreading in of a cooler current of air from the Atlantic, which caused a temporary displacement of the anticyclone, there was a brisk fall of temperature on Sunday, the transition occasioning thunderstorms and heavy rains in places. The anticyclone surged to the north-westward again on Monday, July 14, and there was a return of the bright and hot weather.

A MEMORANDUM forecasting the probable amount of monsoon rainfall in 1924 was submitted in the early part of June to the Government of India by Sir Gilbert T. Walker, the Director-General of Observatories. The monsoon rainfall of India is affected by previous conditions over various parts of the earth. Snow in the mountain region north-west of India is an important feature; the accumulations at the end of May were markedly about normal from Afghanistan to Almora, especially at the higher elevations, and this excess of snow may be expected to retard appreciably the development of the monsoon. Among other factors are the rainfall percentages over Java; these were in defect during the period October to February, which indicates abundant monsoon rainfall in India. For the Peninsula, the indications from S. America, the Cape, Java, S. Rhodesia, Zanzibar, and the Aleutian Islands are this year all favourable. For north-west India most considerations are favourable. Summarising the effects, it is forecasted that there will probably be some delay in the establishment of the Arabian Sea monsoon, particularly in north-west India. In the rainfall of the Peninsula an excess may be expected. The indications for north-west India are said to be conflicting, but in spite of heavy snowfall the rains there are likely to be normal or in excess.

DR. R. F. RUTTAN, director of the Department of Chemistry, McGill University, has been appointed Dean of the Faculty of Graduate Studies and Research to succeed Dr. F. D. Adams, who has resigned from the University. Dr. Ruttan was president of the Royal Society of Canada in 1919 and of the British Society of Chemical Industry in 1922. He was appointed an original member of the Honorary Advisory Council for Scientific and Industrial Research for Canada in 1916. He represented the Dominion at Brussels in 1919 on the International Research Council and was a member of the committee which framed the constitution and statutes of the International Union of Pure and Applied Chemistry. Dr. Ruttan is an active and successful investigator, a good organiser, and has developed a very strong graduate school in chemistry at McGill. He is regarded as an excellent choice for the head of the Graduate Faculty.

W. C. ALLEE refers in *Science* (vol. 59, p. 521, 1924) to his recent two months' visit to Barro Colorado Island, the site of the new station for tropical research in Gatun Lake, Panama Canal Zone. The island was the largest of the old hills rising above the valley of the Chagres River and consequently is now the largest of the islands in the man-made Gatun Lake. Comfortable living quarters have just been erected and equipped so that a small party can live and work with comfort in the jungle, which is of the rain forest type and spreads over the five square miles of the island. Ants and termites are common and offer excellent opportunities for the study of habits and for the collecting of commensals; several new species of the latter have already been found. Peripatus occurs on the island. Birds, lizards, armadillos, peccaries, racoons, night monkeys, white-faced monkeys and black howling monkeys are common and relatively tame, and among other mammals found either on the island or near by are tapirs, sloths and ant-eaters. The station affords an opportunity for the study of the physical conditions under which animals live in this sort of jungle and has the great advantage of ready accessibility—being only two hours' journey from Panama City.

SIR WILLIAM POPE has been elected a foreign member of the Reale Accademia Nazionale dei Lincei of Rome, in the Section of Physics and Chemistry and their Applications.

THE autumn meeting of the Iron and Steel Institute will be held at the British Empire Exhibition, Wembley, on September 4-5. Applications to attend the meeting must be received at the Institute not later than August 15.

WE learn from *Science* that William Gaertner, president of the Gaertner Scientific Corporation, Chicago, has been awarded the Howard N. Potts Gold Medal by the Franklin Institute, "in consideration of his notable achievement as a designer and maker of scientific instruments, materially contributing to the success of the research in physical science."

APPLICATIONS are invited for an inspectorship of agriculture under the Sudan Government. Candidates for the post must have had a thorough practical and scientific training in agriculture and possess the national diploma or a university degree in agriculture. Particulars of the appointment are to be had from the Inspecting Engineer, Egyptian and Sudan Governments, Queen Anne's Chambers, Westminster, S.W.1.

THE Department of Scientific and Industrial Research invites applications for the post of superintendent of its chemical research laboratory. Candidates should have special knowledge of some branch of pure or applied chemistry. Particulars of the duties attaching to the post and a form of application can be obtained from the Secretary, Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1. Applications must reach the department not later than September 30.

THE International Commission on Illumination will hold its sixth session at Geneva from July 21-July 25. The session meets under the presidency of Dr. E. P. Hyde. Twenty-six papers on subjects connected with illumination are being presented, and delegates from America, France, Great Britain, Italy, Japan, Poland, and Switzerland will be present. The papers deal with photometric nomenclature, primary standards of light, heterochromatic photometry, automobile and industrial lighting, and legislation. It is expected that, as a result of the discussions, progress will be made on several problems in which international agreement and co-operation is desirable.

THE annual meeting of the British Medical Association opens with the meeting of the Representative Body on July 18, and on the evening of Tuesday, July 22, Mr. Basil Hall will deliver his presidential address at the Regent Picture House, Manningham Lane. Among the eminent foreign guests who will be present are Dr. Alexis Carrel of New York, Prof. Ignacio Barraquer of Barcelona, and Dr. Van den Bergh of Leyden. Before this address, the president will present the Stewart Prize to Prof. E. Mellanby, of the University of Sheffield, for his important discoveries on the relation between rickets and dietetic deficiency, and the Gold Medal of Merit of the Association (the highest award in the bestowal of the Association) to Dr. H. B. Brackenbury for his arduous and distinguished services to the Association and the medical profession.

THE summer conversazione of the Natural History Museum Staff Association was held on July 2, and was attended by a large number of members and visitors, many of the latter coming from overseas. The remarkable series of specimens which had been arranged by the desire of Dr. W. Bateson, a Trustee of the Museum, to illustrate the variation in characters in three zoological groups—birds, mammals, and molluscs—attracted much attention. Considerable interest was also taken in the selection exhibited from the collection mainly of vertebrate fossils made by the late Mr. R. W. Hooley in the Wealden of the Isle of Wight. This extensive collection has recently been acquired by the Trustees. Other notable exhibits included a new plant genus belonging to the family of Umbelliferæ and collected by the Misses Godman in Central Africa; and a few examples of the splendid photographs taken by Mr. M. Maxwell of the elephant and the rhinoceros.

THE Lecture Bureau of the Selborne Society has already issued its list of lectures for the 1924–25 season. The names of more than fifty lecturers appear in the list; the subjects offered number considerably more than three hundred, and thus afford a very wide field for selection by those desirous of engaging lecturers during the forthcoming season. The Bureau caters for all tastes: literature, art, scenery, folk-lore, commerce, psychology, and many of the branches of natural science are well represented on their list. We note, however, that while physical and biological subjects are named fairly frequently, there is an absence of those concerned with chemical processes. Considering how largely these enter into the industrial life of the present day, we venture to suggest that there are, up and down England, numerous audiences eager for clear information on such topics. Inquiries concerning these lectures should be addressed to the Secretary, Selborne Society, The Hermitage, Hanwell, W.7.

THE Rockefeller Foundation has issued a review of its activities during 1923, compiled by the president, Mr. George E. Vincent. A sum of more than eight million dollars was expended in forwarding public health and medical education in all parts of the world. The work included the support of 636 fellowships, international visits, emergency relief to institutions of 15 European countries, contributions to schools of hygiene, hookworm campaign in conjunction with 20 governments of the world, yellow fever campaign in Brazil, contributions for medical education in Great Britain and other countries, and malaria control in several countries.

IN a lecture given by Mr. T. Thorne Baker at the Royal Society of Arts on "Photography in Science, Industry, and Medicine" (R.S.A. Journal, June 23), which was illustrated by a very large number of examples, the lecturer said that "the plate chemist has learned the secret of the sensitiveness to light of

silver bromide, he can produce an emulsion in gelatin of this unique substance, which shall have a predetermined size of grain, of contrast-giving power and rapidity. He can make it sensitive to all the colours of the spectrum, to the invisible infra-red and ultra-violet rays, to the X-rays and shortest wave motions produced by radium." Mr. Thorne Baker explains that the sudden disappearance of pictures transmitted by telegraph was because the cost of transmission proved to be "altogether prohibitive." He hopes that before long a new system will be available on a really commercial scale—the time of transmission being reduced to 2½ minutes.

We have received No. 118 of Abderhalden's "Handbuch der biologischen Arbeitsmethoden" (Lieferung 118, Abt. 2, Physikalische Methoden, Heft 4. Die meteorologischen Messmethoden, von Walter Georgii; Die Makrophotographie, von Marie Kundt; Farbenphotographie, von Walter Thiem. Pp. 483-618. Berlin und Wien: Urban und Schwarzenberg, 1924. 6·40 Schw. frs.). It deals with meteorological measurements, such as temperature, pressure, moisture, wind-strength, etc.; macro-photography and colour photography. The matter is strictly practical, and not overburdened with a variety of methods or formulæ. In the photographic section, the support and manipulation of the camera and the support of subjects of various kinds are dealt with at length, as well as the numbering of series, as for indexing purposes, the copying of diagrams, engravings, and so on. The few pages on colour photography give just the extra assistance needed for the use of autochrome and "Agfa" colour plates by daylight and artificial light.

Mr. F. S. Spiers, secretary and editor to the Faraday Society and secretary to the Institute of Physics, has moved his office to 90 Great Russell Street, W.C.1 (Telephone, Museum 5718). The publishing office of the *Journal of Scientific Instruments* is now also at this address.

Our Astronomical Column.

The Lesser Magellanic Cloud.—There have already been several estimates published of the distance of this object. Prof. Harlow Shapley (Harv. Coll. Obs., Circ. No. 255) revises these in the light of new photographic determinations of the magnitudes and periods of the numerous Cepheid variables in the Cloud. The results point very consistently to a distance of 31 kiloparsecs or 100,000 light-years. He notes that Dr. R. E. Wilson's researches on the proper motions of galactic Cepheids tend to make the estimated distances of clusters and the Magellanic Clouds smaller by 20 or 30 per cent.; but that this reduction may be cancelled if Kapteyn's suggestion of systematic errors in the accepted proper motions in declination should be correct. He proposes, therefore, to postpone any correction till the question is settled.

The diameter of the Cloud is 6500 light-years, and its depth in the line of sight is presumably of the same order, so that it is no inconsiderable universe in itself. Its brightest stars are estimated to be of absolute magnitude −7·0, and diameter 1000 million kilometres, thus exceeding Betelgeux and Antares in size. It has been found possible to ascertain the general spectral types of some of them: types K5 and M occur among these, and the largest diameters are to be expected in these types.

The Cloud is receding with a speed of 170 km./sec., equivalent to a kiloparsec in 6 million years; Prof. Shapley suggests that it may have been a galactic star cloud 200 million years ago.

Distribution of Energy in Stellar Spectra.—The spectral energy curves of stars of types F5, A, and B have been measured by M. J. Baillaud, *Comptes rendus* of the Paris Academy of Sciences, May 12, and are found to be distributed into three groups, one for each type. The curve of Procyon (F5, dwarf) is the only one of those measured which approximates throughout to the "black body" form; those for types B and A have no relation to a black body curve, whatever temperature is assumed, at any rate for wave-lengths shorter than 500 mμ; it is thus impossible to use the curves for the determination of temperature. The author concludes that the origin of the observed continuous spectrum is not the same for the white stars as for the yellow; for the sun and dwarf stars like Procyon, the continuous spectrum apparently comes from a photosphere consisting of incandescent solid particles; for A and B stars the radiation seems to come from masses of gas at high temperatures; hydrogen and certain metallic vapours have been observed to emit continuous spectra, of a similar nature to those of these stars, in the laboratory. In certain cases, there appears to be a combination of the above sources of radiation; this may be due to the emission of black body radiation by a central nucleus, and of a high peaked continuous spectrum by surrounding gases.

Spiral Structure in Star Clusters.—Attention is directed by Dr. P. ten Bruggencate, in the *Zeitschrift für Physik* for June, to the discovery of remains of spiral structure in the B stars of the star cluster Messier 13, by Freundlich and Heiskannen. Dr. Bruggencate has plotted the bright and the fainter stars separately, on millimeter paper, for Messier 3 and Messier 15; and finds that the 150 bright stars of the former cluster show distinct signs of a spiral structure, while 270 fainter stars indicate an elliptical arrangement, the direction of the major axis of the ellipse being estimated with considerable certainty. Apparently the line joining the two points on either side of the cluster from which the arms of the spiral proceed, coincides in direction with the major axis of the cluster, as is required by the theory of Jeans. For Messier 15 there is not much evidence of spiral structure; but the Bonn catalogue is not sufficiently complete for accurate investigation of this cluster. Messier 37, which is an open cluster, shows Shapley's phenomenon, *i.e.* the giant stars are brighter the redder their colour, which indicates that they have a common origin; the complete catalogue of this cluster by v. Zeipel and Lindgren was employed, and it was divided into four concentric rings, the principal axis of inertia for the B and A stars of each ring being determined by counting. The direction of this axis was found to be constantly twisted in the counter-clockwise direction in proceeding outwards, the total observed twist being a little more than 45°. Thus even in an open cluster remains of a spiral structure may be found when the larger stars belonging to it are examined, the smaller stars which originally had a similar structure having become irregularly scattered.

Research Items.

DISINTEGRATION IN PRIMITIVE SOCIETIES.—Capt. G. Pitt-Rivers, in his presidential address to the Section of Ethnology and Anthropology of the Australasian Association for the Advancement of Science in 1923, which has recently been issued in the Report of the Association, offers some interesting suggestions in reference to tests which might be applied in estimating the trend of development in any given community, referring in particular to the changes which are brought about in a primitive society when in contact with white civilisation. For this purpose a comparison of different cultures and their social and moral systems is not adequate; but a standard or norm is to be found in the tendency to integration or disintegration. Taking, for example, the Papuo-Melanesian and Micronesian cultures, the principal factors of social integration are: (1) the chieftainship; (2) magic and sorcery; (3) the system of exchange of gifts, partly economic, partly ceremonial and non-economic. In the case of each of these the effect of contact with white civilisation has been disintegrative. In Papua the institution of a village policeman as the chief district authority has undermined the position of the chief without ensuring that the substitute shall be of a type to take his place in the native's estimation; while by suppressing sorcery and magic the administration has destroyed the strongest influence which made for law and order.

FORAMINIFERA OF LORD HOWE ISLAND.—Messrs. E. Heron-Allen and A. Earland (Journ. Linn. Soc., Zool., vol. 35, 1924) describe a collection of Foraminifera, made by Prof. R. D. Laurie at Lord Howe Island, South Pacific, which contains 199 species and varieties. Two new genera are described—Craterites, which is related to Orbitolites, and Diffusilina, the neatly constructed test of which and the high proportion of cement in its finished exterior surface indicate affinities with the Lituolidæ, but it has no close relationship to any previously recorded type. The authors direct attention to the profuse occurrence of species in reproduction, both by viviparity—young examples being found in a cavity resulting from the absorption of the internal septa of the test—and by "budding" from the aperture. The material was from the reefless area of the island only, and the authors believe that many species would have been added to the list if a collection had also been made among the reefs and in the lagoon. The material shows that a large proportion of the specimens are not of local origin but are more or less water-worn and have travelled some distance. Many of the species recorded have a wide range, from East Africa through the Malay and Australian seas to the Pacific.

MEDICAL PROTOZOOLOGY.—In a recent lecture on medical zoology (*Amer. Naturalist*, vol. 58, pp. 1-23, 1924) Prof. R. W. Hegner surveyed the recent investigations on protozoa carried on in his department of the Johns Hopkins University. He said that various theories had been put forward to account for relapses in malaria, and that one of these seemed now to be proved, for Dr. Ben-Harel had been able to show, by working on canaries infected with Proteosoma, that when parasites are apparently absent from the blood they exist in small numbers in the spleen and bone-marrow, where they undergo asexual reproduction in a normal manner. He referred to the work of Dr. Taliaferro on *Trypanosoma lewisi* in rats, and stated that pure lines of this species had been obtained by inoculating clean rats with single trypanosomes, and an intensive study had been undertaken of the resistance which the rat offers against infection. There are three manifestations of such resistance: (1) the rate of reproduction of the parasites is retarded until it is inhibited altogether by about the tenth day; (2) a large number of parasites are destroyed between the 10th and 14th days; and (3) the rest of the trypanosomes—non-reproducing adults—are finally destroyed. The first resistance is due to the formation in the blood of the rat of a reaction product which inhibits reproduction of the trypanosomes but does not destroy their vitality; the second resistance is as yet not explicable, but the third—the destruction of the organisms—is brought about by the formation of a lysin. Suggestive observations are recorded on the effects of a change of diet on *Trichomonas muris* in the cæcum of the rat—for when heavily infected rats were put on a well-balanced carnivorous diet for a week, the number of Trichomonas decreased almost to disappearance, apparently owing to alterations in the bacterial content of the cæcum and in the products of their activity. Prof. Hegner suggests that a carnivorous diet might be an effective method of treatment of flagellate dysentery in man, and states that the method has been put into practice in a few cases with "remarkably rapid and satisfactory" effects.

ACIDOPHILUS MILK.—Artificially prepared soured milks have been made use of as articles of diet in various parts of the world from time immemorial, and years ago Metchnikoff introduced the use of milk soured with the Bulgarian bacillus as a preventive of the onset of old age! Recently Prof. L. F. Rettger, of Yale University, has found that the *Bacillus acidophilus* produces a soured milk of considerable value in the treatment of intestinal toxæmias (*Science*: Science Service Supp., June 13). Skimmed cow's milk is boiled and cooled and inoculated with the organism, which is allowed to grow for twenty-four hours. At the end of this time the milk is curdled with a soft curd, and on shaking assumes the consistency of thin cream. Taken daily in quantities of from one to two pints, the fermentive and putrefactive bacteria in the intestines are much reduced in numbers with corresponding benefit in suitable cases.

TEMPERATURE IN THE NETHERLAND INDIES.—In Verh. No. 8, vol. 1, part 5, the Royal Magnetic and Meteorological Observatory of Batavia has recently published a discussion of temperature by Dr. C. Braak in continuation of other discussions on the climate of the Netherland Indies. A brief English summary is given as well as the full discussion in Dutch. Recent observations have been mostly used, as the older observations are generally untrustworthy, owing to defective exposure. Temperature is fairly uniform during the whole year, and in addition to the annual variation of winter and summer there is the influence of the monsoon. Whether the wind blows from south or north it brings air of equal temperature. Rain showers may cool the air temporarily, but generally uniformity of temperature is apparent. For daily differences in the dry season, the maximum temperatures are usually higher than in the wet season and the minimum lower, the daily range being greater in the dry season. The time of the maximum varies with the height above sea level, and the maximum occurs relatively early at the high mountain stations, where night frosts are occasionally noted in August and September. Diurnal variation of mean air temperature from observations in the Archipelago and in the adjacent Indian Ocean gives an extreme range of 0·87° C., while for the sea it is 0·75° C. The average air temperature is 26·05° C., the sea 27·10° C., the sea water being thus 1·05° C. warmer than the air. The decrease of temperature with increasing height in the free atmosphere is discussed, and the variation of soil temperature with depth. Monthly series of isotherms of air and sea over the adjacent waters, and

copious tables and diagrams, are given in the original text. The discussion is of the highest value for the advancement of the world's meteorology, dealing with the temperature of the part discussed in the most complete and scientific manner.

THE SURFACE LAYERS OF OCEANIC WATERS.—After studying the records of the *Challenger* soundings and plotting the density and temperature against depth, M. J. Thoulet has found that there is a limited layer, near the surface of the oceans, in which the denser water, due to evaporation at the surface, sinks, and is mixed by wave action with lighter water, containing less salt, produced by the action of rain, the melting of ice and the inflow of rivers (*Comptus rendus* of the Paris Academy of Sciences, May 12). The mean thickness of this layer of mixture, or of rapid diffusion, varies in different parts of the ocean between 600 and 800 metres, being greater in the tropics than near the poles; a layer of minimum density divides it from the lower oceanic water, where there is only slow diffusion. The paper gives an account of the seasonal variations of this upper layer, which cause a movement of water towards the poles in summer, and a reverse movement in winter. The density in the minimum density layer varies from 1·0289 in hot regions to 1·0253 near the poles, with a mean value of about 1·0275. It is particularly regular in the South Atlantic and the Pacific, where it is rarely so high as 1·0280.

THE VACUUM TUBE DISCHARGE.—In the July issue of the *Philosophical Magazine*, Sir J. J. Thomson puts forward a theory of the electric discharge in gases at very low pressures such as are used in the older X-ray tubes, which is in better agreement with the experimental facts than the theory which depends mainly on the collisions between cathode rays or positive ions and the molecules of the residual gas for the source of ionisation. The process which takes place in the tube is rather as follows. The positive ions on striking the cathode emit radiation which, falling on the cathode, causes a photoelectric emission from the cathode. The electrons emitted acquire a high speed, and cause the molecules of the gas to emit a second radiation, which in turn ionises the molecules it encounters. The recombination of the ions so produced constitutes the negative glow. On this theory, the difference of potential between a point in the dark space and the negative glow is proportional to the square of the distance of the point from the inner edge of the glow, which has been found to be the case by Dr. Aston.

ACTION OF A TRANSVERSE MAGNETIC FIELD ON THE CATHODE DARK SPACE.—A communication from the Physikalisch-Technischen Reichsanstalt in the *Zeitschrift für Physik* for May, by Dr. A. Günther Schulze, describes an ingenious device for obtaining a self-adjusting, plane, horizontal cathode, which allows the magnet poles to be brought fairly close together, and at the same time enables the glow discharge to be produced at a distance from the glass walls, so that it is unaffected by them. A glass tube, diameter 4 cm. and length 28 cm., is closed at one end, half filled with mercury, which forms the cathode, closed by a rubber stopper through which pass a glass tube connecting with the air pump and the connecting wires, and is laid horizontally between the magnet poles, so that the lines of force pass across parallel to the surface of the mercury cathode. The anode is near the stopper, and with a fairly high vacuum the glow discharge is deflected in a narrow band towards the sealed end of the tube. The width of the dark space, measured vertically, is obtained by means of a cathetometer; there is a minimum value for this distance d (*Fallraum*), which for all the gases investigated is near 0·70 mm.; for pressures of not less than 20 mm., d is very little greater than this minimum value with zero magnetic field; but for low pressures it is much larger, and can then be reduced to the minimum value when the field is increased sufficiently.

EXTRA HIGH FREQUENCY γ-RAYS FROM RADIUM.—The secondary β-ray spectrum from lead, excited by the γ-rays of radium and its disintegration products, has been photographed and investigated by M. J. Thibaud (*Comptes rendus* of the Paris Academy of Sciences, May 19). Eight lines have been found, the energy in kilovolts of each being as follows:

1	2	3	4	5	6	7	8
152	203	258	330	516	593	671	1034.

All of these lines correspond with lines in the spectrum of radium and its disintegration products; 1, 2, and 3 are identical with lines found by Ellis to belong to radium-B, 4 has been observed by de Broglie and Cabrera in the spectrum of the same substance, 5 corresponds to a β-ray originating in the K level of radium-C, 6 to one from the L level of the same substance; the difference between the energies of these two lines is 77,000 kilovolts, which agrees with the number, 75,000 kilovolts, calculated from other lines of the radium-C spectrum for these two levels. According to Ellis's theory, these lines may be due to a nuclear γ-ray, with energy 605,000 volts; while line 8 of the lead secondary spectrum, which corresponds to a line from the K level of radium-C, is due to a γ-ray with energy 1,123,000 volts. Lead, which was used as the secondary radiator, is an isotope of radium-B, and the production of lines 1, 2, 3, and 4 in its spectrum is to be expected. That the lines of radium-C are also obtained is regarded as due to the fact that the variation of the energies of the levels of radium-B and C is of the same order as the experimental errors.

SYNTHESIS OF METHANE FROM COAL GAS.—Work on the synthesis of methane from coal gas has been carried out in the laboratories of the South Metropolitan Gas Company, and some results were described at the annual meeting of the Institution of Gas Engineers. The preliminary complete purification of the gas from sulphur compounds necessary to avoid poisoning the catalyst involves the partial elimination of valuable unsaturated hydrocarbons from the gas, and the conversion of part of the carbon monoxide content of the gas to carbon dioxide. The loss resulting from these causes and the heat loss attributable to the exothermicity of the hydrogenation reaction would cause a considerable increase in the cost of the gas produced.

PHOTOGRAPHIC DEVELOPMENT AFTER FIXING.—Messrs. Lumière and Seyewetz have communicated to the Paris Academy of Sciences a method which places development after fixing upon a practical basis, which is recorded in the *British Journal of Photography* of June 27. Hitherto this process has required about ten times the usual exposure, presumably because the substance of the developable image, whatever it may be, is soluble in the "hypo" used for fixing. By adding a little ammonia to the "hypo." and to the wash water, this drawback is overcome. The developer preferred contains sodium sulphite and paraphenylene-diamine in addition to silver nitrate, and yields negatives that recall those on collodion plates in appearance and other characteristics. The developer is exhausted in about an hour, and if more density is required it may then be replaced by a fresh portion, and thus continued up to 10 or 12 hours' duration. By this longer time the particles are about equal in size to those of the original silver bromide of the plate. Photomicrographs are given of the grain produced by development for 1, 3, 7, 24, and 48 hours. Even the coarsest grained plate gives a fine grained image unless development is unduly prolonged or the image is intensified.

The Kelvin Centenary.

IN the presence of a large and distinguished company, including delegates from the principal scientific societies of Great Britain, the British Dominions, Belgium, Denmark, France, Italy, Japan, Mexico, the Netherlands, Norway, Poland, Russia, Spain, Sweden, Switzerland, and the United States of America, Sir Charles Morgan (president of the Institution of Civil Engineers) handed the Kelvin medal to Prof. Elihu Thomson in the great hall of the Institution of Civil Engineers on Thursday, July 10.

In making the presentation, Sir Charles Morgan explained that the medal (Fig. 1) was founded in 1914, principally by British and American engineers, to commemorate the advancement by Lord Kelvin of those branches of science which are especially applicable to engineering. The award is dealt with by a committee of the presidents of the representative British engineering institutions, after their consideration of recommendations received from similar bodies in all parts of the world, and, in accordance with the terms of the trust, it is made to the person whom the committee finds to be the most worthy to receive this recognition of pre-eminence in the branches of engineering with which Lord Kelvin's scientific work and researches were identified. The only previous award of the medal was that made in 1920 to Dr. W. C. Unwin, whom he was glad to see present. He reminded his hearers that Prof. Elihu Thomson has been connected with the applications of electricity to lighting and power from the early days of the Thomson-Houston arc lighting system to the vast present-day activities of the General Electric Company of Schenectady. Prof. Thomson has made far-reaching discoveries relating to alternating and high-frequency currents and was a pioneer in electrical resistance welding. A past president of the American Institute of Electrical Engineers, he has been the recipient of many high honours. In receiving the medal, Prof. Elihu Thomson said that he regarded the award as a compliment not only of a personal nature but also to the whole American electrical engineering profession. He liked to think of Lord Kelvin as the supreme example of what a man of engineering science could be.

Sir Richard Glazebrook then took the chair and directed attention to the great progress achieved during the hundred years that they were looking back upon. To this progress, no one had contributed more than the great man whose memory they were met to honour that day. The celebrations originated in a suggestion of Dr. Alexander Russell (president of the Institution of Electrical Engineers), but they were being taken part in by a long list of British institutions and by delegates from foreign societies, who had come from all parts of the world to do honour to Lord Kelvin's name. The chairman then received addresses in writing from a large number of foreign delegates who were present.

Sir Joseph Thomson.

Sir Joseph Thomson then proceeded to deliver the Kelvin oration. In his opening remarks, he characterised Lord Kelvin as the Admirable Crichton of physical science. A great physicist, he was at the same time a great mathematician and a great engineer. He could make inventions as well as he could write text-books, and could take out patents as well as he could write papers. Few men had sprung to fame at such an early age. Born at Belfast, where his father was professor of mathematics, he commenced his studies at Glasgow at ten years of age, when his lifelong connexion with that city and university began. Before he was eleven he had won two prizes in mathematics, and before he was thirteen he had gained further distinction in this subject as well as in natural philosophy and logic. During these early years, his thoughts were turned to two subjects which were destined to play great parts in his subsequent career, the figure of the earth and Fourier's theorem. His later work with regard to the former produced one of his most important contributions to physics, and the latter formed the underlying basis of much of his other work. William Thomson, as he then was, went into residence at Peterhouse, Cambridge, in 1842, and was soon recognised as the most brilliant mathematician of his year, although he had to be content with the position of second wrangler in the mathematical tripos of 1845. He was, however, easily first in the examination for the Smith's Prize in the following year. After taking his degree, he worked for a few months in the laboratory of Regnault in Paris. This had a great influence on his career, not only in familiarising him with laboratory methods but also in introducing him to the work of Sadi Carnot, on which the second law of thermodynamics

was afterwards based. In October 1846 he was appointed to the chair of natural philosophy at Glasgow, which he held with such brilliance for fifty-three years, soon extending the meagre facilities for experimental demonstration which he found there. Throughout his professorial career he may be said to have acted rather as an inspirer than as an instructor. He filled the ablest students with enthusiasm, the others with despair.

The decade of 1850–60 saw the establishment of the second law of thermodynamics, and Kelvin's work in this connexion has claim to be regarded as the most important of his many important contributions to physics. Continuing this work, he published in 1851 a paper expounding the position of thermodynamics in a masterly way, introducing the idea of an absolute scale of temperature corresponding to the readings of the gas thermometer. He also found time to devote to thermo-electricity and magnetic and other problems. It is important to record that his paper on transient electric currents in 1853 revealed the discovery of the oscillatory nature of the discharge of a condenser in certain circumstances, which is the basis upon which the whole study of electrical oscillations and wireless telegraphy and telephony is founded. In further papers he dealt without intermission with discoveries of fundamental importance in nearly every branch of physics. An outstanding feature of his equipment for the attack of dynamical problems was his engineer's intuition of how matter in motion would behave. The secret of his success in applying mathematics to physical problems was that he knew what to expect. With his striking originality, he was greater in developing his own methods than in following the lead of previous workers. In this respect he might be described as a good radiator but a bad absorber. For sixty years he worked at the elucidation of the theory of the luminiferous ether, and no small proportion of his total of 661 papers is devoted to this subject. Although he had to admit failure as regards direct results, a good deal of benefit arose indirectly from these investigations. The lecturer referred briefly to the new outlook opened up in the teaching of dynamics, etc., by the publication of Thomson and Tait's work on natural philosophy, to Lord Kelvin's fascination by gyrostatic problems, and his theory of the age of the earth, which was afterwards invalidated by the discovery of radio-activity.

It was in 1855 that Kelvin first turned his attention to submarine telegraphy and took up the study of the propagation and retardation of currents in cables, and his first connexion with Atlantic cable enterprise was his election, in 1855, as a director of the Atlantic Telegraph Co. to represent the Scottish shareholders. He soon took a more active part and accompanied the original unsuccessful expedition on the *Agamemnon* in 1857, and the expedition in the following year, when only brief communication was established, as well as the final successful expedition of 1866. It is well known that the conversion of failure into success was in no small degree due to the ability and courage with which he faced the problems involved and to the instruments, including the marine galvanometer and the siphon recorder, which he devised. His instruments of another type revolutionised the practice of electrical measurement generally; and the formation of the British Association Committee of 1861 on electrical standards was mainly due to him. It was he who devised the first method of measuring resistance absolutely by the spinning coil.

Kelvin was a keen yachtsman, and his interest in the sea led him to make most important contributions to navigation in his deep-sea sounding machine, tide predictor, and other apparatus. In addition to the direct results of his investigations, he produced great effect on scientific progress indirectly by the enthusiasm which he stimulated in others. This was very particularly seen at the meetings of Section A of the British Association, which his personality filled with life and interest. Kelvin was a man of outstanding vigour in the union of theory and practice and in untiring devotion to a great idea.

Dr. Alexander Russell.

An inspiring account of Kelvin's life and work was given by Dr. Alexander Russell in an oration delivered at the centenary commemoration at the University of Glasgow on June 25 and published in pamphlet form. Dr. Russell, himself an old student of Glasgow who attended Kelvin's lectures, spoke of Kelvin's belief that the chief importance of science lay in its applications for the material benefit of the human race, and his unbounded enthusiasm in applying it to ameliorate our everyday life. He was impatient of the slow progress made in improving means of communication, systems of lighting, and methods of transport by land and sea. His vivid imagination saw the world as it might be if science, engineering, and human labour had no limitations.

Dr. Russell proceeded to outline Kelvin's early years at Belfast, his brilliant career as a student at Glasgow and Cambridge, and his subsequent greatness as a professor, and spoke of the importance of his original work in mathematical physics generally and particularly in thermodynamics, submarine telegraphy, terrestrial magnetism, and the oscillatory discharge of the Leyden jar, and his applications of the theories of gyrostatic action and vortex motion. Kelvin was also greatly interested in atmospheric electricity and his well-known navigational instruments include his deep-sea sounding machine, his tide predictors and analysers, and his famous magnetic mariner's compass. It is not so generally known that he was also a pioneer of the gyrostatic compass, of which he made a model in 1884. The wonderful series of electrical measuring instruments designed by Kelvin bears witness to his energy, his inventive skill, and his practical genius. His electrometers and electrostatic voltmeters are in use in every country of the world to-day. In 1878 he pointed out how simply electrical energy could be transmitted over great distances, and his law determining the size of mains has done much towards cheapening the cost of electrical distribution. Attention was also directed to the importance of his work on electrical units and standards. "For the number, variety, and importance of his great contributions to science," continued Dr. Russell, "he stands without a rival. His works are a gift to universal Humanity. Had it not been for Kelvin the world would have been perceptibly poorer to-day. . . . And as the years roll on our debt to him grows ever greater."

Overseas Electrical Engineers.

A large party of representatives of overseas electrical engineering institutions who are visiting England, partly in connexion with the World Power Conference at Wembley, was entertained during the past week by the Institution of Electrical Engineers. The proceedings, which were to some extent combined with the Kelvin centenary celebrations, were inaugurated on Wednesday, July 9, at a reception at the Institution building on the Victoria Embankment, when the president, Dr. Alexander Russell, gave a brief address of welcome to the visitors. In the course of his address, he emphasised the truly international character of electrical science as evidenced by the names of our electrical units commemorating

great workers from many lands. It was particularly fitting that their visit coincided with the Kelvin centenary celebrations and the award of the Kelvin medal to Prof. Elihu Thomson, the successor of Lord Kelvin as chairman of the International Electrotechnical Commission. In another American representative they were glad to welcome Prof. Kennelly, of Harvard. Prof. Keith (secretary of the Engineering Institute of Canada) replied on behalf of the visitors, and in paying tribute to the work of Lord Kelvin referred to the part that he had played in the early days of the harnessing of Niagara. Representatives were present from the following societies: The American Institute of Electrical Engineers, Associacion de Ingenieros de Caminos, Canales y Puertos (Madrid), Associazione Elettrotecnica Italiana, Dansk Ingenirforening, Norske Ingenirforening, Engineering Institute of Canada, Institute of Engineers (India), Institution of Engineers (Australia), Koninklijk Institut van Ingenieurs (Holland), Schweizerischer Electrotechnischer Verein, Société Belge des Électriciens, Société Française des Électriciens, South African Institute of Electrical Engineers, Svenska Teknologforeningen, Vereening van Directeuren van Electricitatabedrijvenin Nederland, and other bodies.

The reception was followed by a luncheon at the Hotel Cecil, at which some three hundred members and guests sat down. The toast of the visitors was proposed by Mr. Ll. B. Atkinson (past president), who included in his speech a few words of welcome in nearly every language of the visitors, and was responded to by Mr. J. W. Lieb (past president of the American Institute of Electrical Engineers). Most of the visitors attended at the presentation of the Kelvin medal to Prof. Elihu Thomson and the delivery of the Kelvin oration by Sir Joseph Thomson at the Institution of Civil Engineers in the afternoon. The full programme of entertainment of the visitors, as we have already announced, included the Kelvin banquet on Friday, July 11, and visits to Wembley, Cambridge, the Birmingham district, and Windsor, and a lunch on Tuesday by invitation of Lord Ashfield, chairman of the Underground Electric Railways of London, Ltd.

Electrical Progress and its Unsolved Problems.

THE above was the title of the James Forrest lecture delivered at the Institution of Civil Engineers on Tuesday, July 8, by Prof. Elihu Thomson. The lecturer recalled Col. Crompton's James Forrest lecture in 1905 entitled "Unsolved Problems in Electrical Engineering," and proposed to deal with similar matters from the present point of view, directing attention to the recent advances in various departments of electrical work.

Speaking first of the electrical phenomena in Nature, Prof. Thomson referred to terrestrial magnetism, and made the suggestion that the oxygen in the atmosphere, being magnetic in property, must in a measure influence the direction of the lines of dip within the atmospheric layer. Of all natural electrical manifestations the thunderstorm is the source of most difficulty in electrical undertakings. The view of its cause now generally adopted is that of Simpson, making it a water-drop phenomenon. With the rapid passage of condensed drops through an uprising current of air, a fine spray is torn from them carrying a negative charge, and leaving the diminishing drops positively charged. The lecturer inclined to the view that the lightning flash is more of a steep wave-front discharge in one direction than a true oscillatory discharge. This, however, does not prevent structures capable of oscillation being activated by the shock of a heavy discharge. There are still many unsolved problems connected with protection of electrical apparatus and lines from the effects of lightning, but with increased transmission voltages and their greater degree of insulation, lightning troubles may be expected to diminish. For the protection of buildings, however, there is ample security in the intelligent application of the principle of providing a best path to earth. The so-called "ribbon" discharges, or successive discharges down the same ionised air streak, stationary or travelling with the wind, are the most dangerous. With regard to the explanation of globular lightning, which undoubtedly exists, little progress has been made.

Magnetic storms and auroræ are now generally recognised to be connected in some way with sun-spot conditions. It would seem that from the spot areas, streams of electrified particles are projected at speeds possibly up to 2000 miles per sec. If the earth is moving in its orbit near such a stream a disturbance of the magnetic field is inevitable. When the earth is directly immersed in the stream, the outer thin envelope of gas entangles the electric particles, resulting in a decided elevation of charge or potential of the outer partially conducting layer. This charge may be carried around with the revolving earth, so that on the dark side a discharge takes place into the shadow of the earth, continuing until the received charge is exhausted, or there is no further entrance or absorption of ions on the side towards the sun. This would account for the fact that most short-lived auroræ begin in the evening, and for the induced effect on telegraph lines during the disturbance.

The old phenomenon of St. Elmo's fire has in late years a counterpart in the corona surrounding high-voltage lines, which, since it involves a loss of energy, should be avoided by increasing the wire diameter or otherwise, such as possibly by jacketing the line with hollow beads or shells. The same potential limitation exists in wireless antennæ, where corona discharge is apt to produce distortion as well as loss of energy.

Turning to questions of transmission of energy, Prof. Thomson said that in the broadest sense all transmission of energy is electrical in its nature, as all the properties of matter now seem to be fundamentally electric. He dealt briefly with the conditions of transmission lines, recalling that the flow of energy itself is not in the conducting wire but in the space surrounding it. In ordinary low-frequency currents little of the energy is radiated away into the space. At high frequencies the radiation loss is a measurable quantity, and at the highest frequencies, as used in wireless transmission, practically all the energy is radiated. In the past few years, the advances made in this form of electric transmission have given rise to a new art of unprecedented importance in the future. The lecturer dwelt upon some of the features of this advance, particularly in the development of the three-electrode thermionic valve, and mentioned interference of conditions of land surface, atmospherics, and "fading" as among the unsolved problems. He was inclined to think that the last-mentioned may be caused by displacement of phase relations by changes in the electrical condition of the lower atmosphere preceding distant lightning discharges.

Outside of high-frequency work, most of electrical engineering is based on the magnetic properties of iron, and although no great advance on the high figures of efficiency now attainable may be expected,

no definite limit can yet be set upon the reduction of iron losses by improved material. The recently discovered "Perm-Alloy," which magnetically saturates even in the earth's field alone, points the way to improvements in instruments, and raises questions as to the possible discovery of other alloys with equally surprising magnetic qualities. It is not to be expected that any real substitute for copper as a conductor can be found, although aluminium can sometimes be substituted for transmission lines, and its higher resistance is even an advantage in certain cases of rotors of induction motors. In the matter of insulation, however, there will always remain room for further advances. The difficulties in the design of large generators are now mechanical rather than electrical.

Applications of electric transmission of power of another kind were mentioned in electric ship propulsion now applied to the largest battleships, to transmit power from the high-speed turbines to the low-speed propellers with advantages of efficiency and facility of control, and in other craft in connexion with Diesel and other oil engines as well as on land in Diesel locomotives, "petrol electric" automobiles, etc. The still unsolved problem of continuous or alternating current motors for railway traction was also dealt with, and other points in connexion with electric traction referred to included modern methods for suppressing flashing over at the commutators of rotary converters, and improved forms of control, including automatic control of sub-stations. In connexion with the beginnings of so-called "super-power" systems, an important problem is the control of power factor, and there is room for improved construction of static condensers for this purpose.

Passing on to the application of electricity for the production of heat, the lecturer indicated that it is more in localised heating for special purposes, or in the production of very high temperatures, that the field of electricity lies, than for the general warming of buildings. He dealt at some length with the possibilities of electric resistance welding of the "flash" and "spot" welding varieties, which is fast superseding riveting in a great variety of work. Arc welding has also considerable application. In electric furnace work a recent development is the Northrup high-frequency induction furnace in which iron cores are dispensed with and currents induced in the crucible at a frequency of the order of 10,000 cycles per sec. It is possible that currents of the necessary high frequency may be provided by valve or arc generators instead of special high-frequency alternators. The great advantage of electric heating in furnaces is the excellent control of temperatures and exclusion of gases. Electric heating can be carried out in vacuo, or, on the other hand, high pressures may be used with suitable furnace design.

Dealing with electric lighting, the lecturer traced the progress from the open carbon arc to modern magnetite and other arc lamps considerably used in America, and often in conjunction with mercury vapour rectifiers, and in the incandescent lamp, from the carbon filament lamp of forty years ago to the gas-filled tungsten lamp of to-day. It would seem, he said, that but little further advance in this field is to be expected. There is, however, much room for improvement in the application of the lighting units in illumination.

Reviewing the situation regarding storage batteries, Prof. Thomson expressed the view that the ideal has not yet been reached either in the lead battery or in the nickel-iron cell, both of which have serious disadvantages, especially for electric vehicle work. Even the latter, useful as it may be in certain circumstances, does not provide a true solution of the storage battery problem; "perhaps," he continued, "there is no solution possible."

There are many directions in which it is impossible to predict the developments of the future. "Who is there," Prof. Thomson said, "to tell us of the momentous issues and events which may arise out of the studies in pure science, of atomic and molecular structure, and the energy relations involved, which have become in large measure the chief study in physical science of our day? Perhaps our comparatively feeble beginnings in thermionic emission and the manipulation, so to speak, of electric ions, infinitesimally small though they be, coupled with the knowledge of the electric structure of matter in all its forms, may be the foundation of a greater superscience of electricity of enormous importance to the future achievements."

University and Educational Intelligence.

ABERDEEN.—At the Summer Graduation on July 10 the honorary degree of LL.D. was conferred on Dr. Michael Comport Grabham. Dr. Grabham delivered a lecture on July 9 on the "Natural History of Madeira."

The degree of D.Sc. was conferred on Mr. H. E. Magee, for a thesis on "The Influence of Food on the Respiratory Exchange of the Ruminant."

EDINBURGH.—The following are among the changes announced recently in the staff of the University: Prof. J. C. Meakins, professor of therapeutics, is leaving in September to take up his duties as professor of medicine, McGill University, and physician-in-chief in the Royal Victoria Hospital, Montreal; Dr. Bevan B. Baker, lecturer in mathematics, is resigning on being appointed to the chair of mathematics in the Royal Holloway College; Dr. O. S. Gibbs, lecturer in materia medica, has left to take up duties as professor of this subject in Dalhousie University, Halifax.

Dr. Frederick Walker, research student in the Geological Department of the University, has been awarded a Rockefeller Travelling Fellowship by the International Education Board. Dr. Walker will undertake petrological research in the Geophysical Laboratory of the Carnegie Institution of Washington.

LONDON.—The hundredth anniversary of the foundation of University College will be celebrated in 1926, and Sir Gregory Foster asks members and friends of the College to send records, reminiscences, pictures, photographs, etc., which are being collected with a view to the production of a history of the College as a part of the Centenary Celebrations. All documents will, in due course, be returned unless the owners desire to present them for the College archives. Communications and parcels (marked "Centenary") should be sent to Sir Gregory Foster at the College.

The Sharpey Physiological Scholarship, of the annual value of 160*l*., founded in memory of Prof. William Sharpey, will shortly be filled, on the recommendation of the Faculty of Medical Sciences of University College, London. The Scholar has opportunities for research, and takes a small share in teaching and demonstrating to students. Applications should be sent to the Secretary of University College, London (Gower Street, London, W.C.1), not later than Saturday, July 26.

ST. ANDREWS.—Applications are invited for the post of lecturer in chemistry in University College, Dundee. Preference will be given to candidates who have specialised in physical chemistry. Applications should be received (in triplicate) by the Secretary of the University by, at latest, August 31.

SHEFFIELD.—The following appointments have been made: Dr. G. A. Clark, to a lectureship in

physiology; Mr. E. F. Baxter, to an assistant lectureship in mathematics.

THE Technical College, Bradford, invites applications for the headship of its newly established department of commerce and banking. Particulars of the post and forms of application may be obtained from the principal, to whom the completed forms must be returned by, at latest, July 28.

THE British Research Association for the Woollen and Worsted Industries is inviting applications, to be received not later than July 31, for research fellowships and advanced scholarships. The fellowships will each be of the maximum annual value of 200*l.*, and are tenable, in the first place, for one year, at an educational institution or elsewhere if suitable resources are available. The advanced scholarships are open to students and others, and are designed to enable the scholar to specialise. Courses of training in research work should generally be included in a candidate's proposed curriculum. Applications, with particulars of past records, proposed course of work, and so on, should be addressed to the Secretary, British Research Association for the Woollen and Worsted Industries, Torringdon, Headingley, Leeds.

EDUCATIONAL RESEARCH appears to have been pursued during the past two or three years with extraordinary enthusiasm in the United States. According to the Biennial Survey, 1920–22, of the Bureau of Education (Bulletin, 1923, No. 42) no less than 80 city, state, and university bureaus for educational research have been maintained, experiments were extensively carried on in all phases of school administration and instruction in numerous institutions, including 22 college and university laboratory schools and about 50 experimental schools for "progressive education," while from numerous presses issued an abundant stream of articles, monograph series, reports, and books. Among the national educational organisations which play a prominent part in promoting educational research are the American Council on Education (now closely associated with the American University Union in Europe), which studies the larger questions of educational policy, the Educational Research Association, the National Society for the Study of Education, the National Society of College Teachers of Education, the Carnegie Foundation for the Advancement of Teaching, and many others. The Bibliography appended to the Bulletin comprises 543 items. Those classified under organisation and administration deal largely with plans for classification in ability groups to the end that America may have no mute inglorious Miltons.

THE following awards, tenable at the Imperial College of Science and Technology, South Kensington, during the year 1924–25, have been made by the Governing Body of the College: (*a*) The Henry George Plimmer Fellowship in pathology to Mr. H. R. Hewer, for a continuation of his research on "The Rôle of Stimuli received by the Eye in the Colour Changes of Amphibia and Nerve Supply of the Pituitary"; value about 300*l.* (renewal). (*b*) The Gas Light and Coke Company's Research Fellowship, established by the Company for the purpose of encouraging experimental research in relation to carbonisation, gaseous fuels and combustion, to Mr. F. R. Weston, for a continuation of his research on "The Spectroscopic Investigation of the Flames of Carbon Monoxide and Hydrogen and matters cognate thereto"; value 200*l.* (renewal). By the Trustees of the Beit Fellowships for Scientific Research: Research Fellowships of the value of 250*l.* each to Mr. O. M. B. Bulman, for a continuation of his work on "Stratigraphical Geology; The Fauna of the Shineton Shales" (renewal); Dr. W. E. Downey, for research on "Photochemical Problems"; Mr. L. A. Harvey, for research on "The Nature and Function of the Cytoplastic Inclusions (Mitochondria and Golgi Bodies) in the Cells of Vertebrates"; Mr. R. Quarendon, for research on "The Combustion of Gases in Nitrous Oxide."

THE *University Bulletin* issued by the Association of University Teachers has until recently been confined mainly to recording the activities of the Association. The June number includes several articles of a more general nature. Among these is one by Dr. Brodetsky, reader in mathematics in the University of Leeds, on the anti-Jewish policy said to be prevalent in certain universities in Poland and Austria. The admission of Jews to these universities is severely restricted by applying what is known as the "Numerus clausus" principle, which consists in limiting the proportion of students belonging to a particular race to the ratio between the total number of persons of that race in the country and the total population of the country. Many Jews have in consequence gone from Austria to Italian universities, where they are welcomed. In an article on "A new residential university," Principal Childs, of University College, Reading, describes the circumstances in which his college is renewing its application for the grant of a university charter. Faculty organisation is discussed by Mr. C. B. Fawcett, reader in geography in the University of Leeds, who advocates reversion on the part of the newer universities to the medieval plan of a general faculty for all non-professional studies and the discontinuance of the practice of awarding several different first degrees—B.A., B.Sc., B.Com., a practice which makes for confusion and misunderstanding, and obscures the essential unity of knowledge.

THE progress of engineering education in India in recent years cannot be said to have kept pace with industrial developments. The official quinquennial Report on Education in India, 1917–22, shows that although during this period expenditure on colleges of engineering and other technical and industrial schools increased by 80 per cent., the number of students in the four Government engineering colleges decreased from 1319 to 1236, and in the other institutions increased only from 13,202 to 15,000. Doubtless there is in India a considerable amount of education in engineering which does not figure in the official returns, but in view of the extent and importance of industrial enterprises already established and the boundless field open to development, these figures must be regarded as astonishingly small, and suggest the question: What would have been the condition of India to-day if the Government's expenditure during the past fifty years on education had been directed by a policy aiming primarily at the development of the material resources of the country instead of being devoted almost exclusively to the dubious benefits of literary curricula on the lines of those of western schools. In Western India, there are signs of a growing appreciation of the benefits of engineering and other technical education, there being keen competition for admission to such institutions as the N.E.D. Civil Engineering College at Karachi, the Victoria Jubilee Technical Institute of Bombay, and the Poona Engineering College, notwithstanding that comparatively high fees are charged.

Early Science at the Royal Society.

July 17, 1661. Sir Paul Neile having mentioned, that the king had, within four days past, desired to have a reason assigned, why the sensitive plants stir and contract themselves upon being touched; it was resolved, that Dr. Wilkins, Dr. Clarke, Mr. Boyle, Mr. Evelyn, and Dr. Goddard, be curators for examining the fact relating to those plants.

July 20, 1664. Notice being given, that some ships were ready for Guinea, it was desired, that such, as had inquiries to be made in those parts, might prepare them against the next meeting.

1687. Mr. Hooke shewed the experiment of vibration of the rods, as a pendulum, which was by suspending a large Indian-cane of about thirty feet long by two pack-threads about eight feet in length: by which it was plain how the weight of such rods or poles for communication of traction or pulsion at a distance might not only be made to move freely and with ease, but also be in the nature of a sway. The same thing was also tried with a large scaffold-pole of about forty feet long.

July 22, 1663. Sir Robert Moray mentioned, that the king had made an experiment of keeping a sturgeon in fresh water in St. James's Park for a whole year: it was moved to kill it, and to see how it would eat.—He related that prince Rupert had made a new kind of gunpowder, in strength so far exceeding the best English powder, that trial being made with a powder-trier, it was found to be in the proportion of 21 to 2. It was desired, that a trial of it might be made before the society.

1669. The society being made acquainted by Mr. Oldenburg, that Mr. Edward Diggs intended to go shortly to Virginia, and offered his services for philosophical purposes; it was ordered that the inquiries formerly drawn up for that country should be recommended to him.

July 23, 1662. The amanuensis was ordered to translate from the French Monsieur Huygen's letter to Sir Robert Moray, dated at the Hague, July 14, 1662, containing some objections to some parts of Mr. Boyle's "Defence of the doctrine touching the spring of the air" against Franciscus Linus and Mr. Hobbes.

1684. Upon a complaint of Mr. Flamstead, that he had been reflected upon by Mr. Hooke in the minutes of the society, it was ordered that a line should be drawn through the places complained of, and that there should be written on the side, "cancelled by order of council": and that the journal-book should be brought to the next meeting of the council, who should see it done.

July 24, 1679. Mr. Haak produced a book intitled "Propositions of Optic Glasses," printed at the theatre at Oxford. Mr. Hooke who had read somewhat of the book, said, that he had not found anything in it, which was new, and that it contained some propositions about the place of the image, which were not true: that it came far short of the theory of optics now well known, which he conceived to have been first well understood by Kepler, and highly improved by Des Cartes.

July 25, 1667. The experiment of opening the thorax of a dog made at the last meeting not having succeeded, it was ordered to be made again at the next; and Dr. King was desired to bring in writing an account of that whole operation, though it failed.

July 26, 1682. Dr. Grew read a letter from Dr. Coga, Vice-chancellor of the university of Cambridge, wherein he mentioned, that Hevelius's last book was not to be found in that university.

Societies and Academies.

LONDON.

Physical Society, June 13.—Mr. F. E. Smith in the chair.—G. E. **Bairsto**: On a method for the synchronous and instantaneous illumination of objects rotating or vibrating at very high speeds. It is capable of giving instantaneous photographic records, and gives a precision of the order of half a microsecond. It is much more precise and able to give a more intense spark than any contact breaker and coil method.—E. A. **Owen, N. Fleming,** and Miss W. E. **Page**: The absorption and scattering of γ-rays. The absorption and scattering of γ-rays from radium filtered through 23 mm. of lead have been measured in magnesium, aluminium, zinc, tin, and lead. Assuming that the mean effective wave-length of the radiation employed is 0·021 Å, the experimental results are consistent with the following statements: (i.) When γ-rays traverse matter, the characteristic radiations of the absorbing medium are excited; (ii.) the atomic fluorescent absorption coefficient of γ-rays depends upon the wave-length of the incident radiation and the atomic number of the absorber according to the law $\tau/\rho.\omega = K\lambda^3 N^4$, which holds for X-rays; (iii.) the radiations which accompany this fluorescent absorption are the characteristic radiations of the K, L, M, . . . series of the absorbing elements; (iv.) the absorption of γ-rays in light elements is due almost entirely to scattering; (v.) the pure atomic scattering absorption coefficient is proportional to the atomic number of the absorber; (vi.) in addition to fluorescent and scattering absorption, a true absorption exists, the atomic coefficient of which is proportional to the atomic number. Compton's formulæ would account for the experimental results if the wave-length of the incident radiation were 0·020 Å. Jauncey's formulæ would require the wave-length to be 0·029 Å.—W. N. **Bond**: The flow of compressible fluids, treated dimensionally. The method of dimensions treatment that is applicable to the pressure gradient at a point in a system through which non-compressible fluids of finite viscosity are passed, is extended by means of the thermo-dynamical equations for gas flow to the case where appreciable changes in density of the fluid occur, but where no heat passes across the walls of the system. The theory is developed in detail only for the case of flow through a straight parallel-walled tube, and has been tested by experiments in which water and air at high velocities pass through small tubes. The air in some experiments had a velocity of more than two-thirds of the velocity of sound in the air. Errors due to moisture, pulsating flow, heat conduction through the walls, and proximity to the entrance to the tube are small; an error of moderate amount is attributed to the partial neglect of the variation of the variables over the transverse section of the tube.—D. B. **Deodhar**: Note on Israj, a remarkable Indian stringed instrument.

Aristotelian Society, June 16.—Prof. T. Percy Nunn, president, in the chair.—A. D. **Lindsay**: Sovereignty. The theory of sovereignty is the storm-centre of political theory. For one school it is inherent in the very conception of government, for another it is nothing but a stone of stumbling, an anachronistic theory to be got out of the way as the essential preliminary to any solution of social questions. Austin approaches the doctrine of sovereignty with the purpose of defining law. Law is essentially a command and depends therefore on a distinction between the sovereign and the subjects. The originality of his theory is that he gives up all attempts to derive the

right of the sovereign from a supposed social contract, and bases it on the previous relation between him who commands and him who obeys. The command is a law consisting in the fact that the person who obeys has been in the habit of obeying the person who commands. Sovereignty is thus based on fact. As constitutional government developed, political theorists tried to describe it in terms of sovereignty. They invented a new kind of person, the people, the general will, the state or the nation, which they distinguished from the individuals composing the community. Bosanquet's "Philosophical Theory of the State" is a theory of sovereignty which he describes as "the general will" and represents as diametrically opposed to the Austinian. He is dealing, however, with a quite different question. He is showing that the real basis of law, as of everything else in society, is the whole of society. What is wanted is a link between this common life of society and the political machinery. The true theory of the sovereignty of the constitution maintains that the link between the social and juristic aspect of the State is the adherence by the great mass of the members of a society to a definite principle of settling differences.

Mineralogical Society, June 17.—Dr. H. H. Thomas, vice-president, in the chair.—Miklós **Vendl**: The chemical composition and optical properties of a basaltic hornblende from Hungary. Complete determinations were made, all on the same sample of material, of crystals of a black hornblende occurring in volcanic tuff near Lake Balaton. The mineral is rich in titania, alumina, ferric iron, and alkalis, and the composition is expressed by the mixing of simple metasilicate molecules (including 14·62 per cent. H_2SiO_3) with aluminate (14·40 per cent. $MgAl_2O_4$) and ferrate (4·32 per cent. $MgFe_2O_4$).—G. **Abbott** and W. A. **Richardson**: The micropetrography of the structures of the magnesian limestone of Fulwell. The structures of the magnesian limestone show a wide variety of forms ranging from simple spherical concretions to highly complex coral-like masses. The more complex types are built up by a combination of rods, tubes, and bars. The microstructure shows more uniformity. The prevailing type is finely granular but crystalline. Where impurities or lines of pigmentation are present the matrix becomes quite microcrystalline as a rule, whilst on the borders of cavities there is a coarser growth. Banded pigmented forms show the same structure as banded chert. Spheroids have either a coralloid structure, or if solid are microcrystalline at the centre with a radial crystallisation towards the surface. The microstructure by itself throws little light on the origin.

Royal Statistical Society, June 17.—J. **Hilton**: An inquiry by sample: an experiment and its results. At the end of 1923 a need was felt of a more detailed and intimate analysis of the million and a quarter or more workpeople in Great Britain who were then being returned week by week as unemployed; and it was evident that such an investigation must be by sample, and that the information desired was of a kind that necessitated personal interviews. It was decided to "tab" every hundredth claim on the live claim file at each Exchange, and invite the claimants thus indicated to attend in the manager's room for interview. Every Exchange was given a different point on its live claims file at which to start, and the starting points were distributed as evenly as possible over the whole occupational classification. The interviews took place in the week ended November 10, 1923, and 9997 reports were received. Comparison with the results of previous inquiries showed that the 1 per cent. sample is nowhere very wide of the mark, and has answered most of its purposes quite as well as a 10 per cent. or 33 per cent. inquiry. The sample only becomes untrustworthy when very small absolute numbers are involved.

Royal Meteorological Society, June 18.—Mr. C. J. P. Cave, president, in the chair.—C. K. M. **Douglas**: Further researches into the European upper air data, with special reference to the life history of cyclones. The temperature in the troposphere is much higher over a Bjerknes' "warm sector" than over the other parts of a cyclone. This leads to the conclusion that a cyclone is superficial in its initial stages. Relevant observations are few, since the development of a cyclone usually takes place in the Atlantic. A large part of the great increase of kinetic energy observed when a cyclone develops is supplied by a convectional overturning between adjacent warm and cold masses of air. The cold mass must have a depth of fully 6 or 7 kilometres, or about the depth of the troposphere in high latitudes in winter. In an appendix it is shown, by means of a criterion due to L. F. Richardson, that an inversion can only exist at a very small angle with the horizontal without becoming increasingly turbulent, a conclusion which is confirmed by observation. In a developing cyclone, the slope of the surface of separation between the cold and warm masses is of the order of 1 in 50, and the inversion is inevitably destroyed by mixing.—Miss L. F. **Lewis**: The effect of the source of air on its temperature at 4000 feet and 10,000 feet. During the winter months, the chief factor in determining the temperature of the air up to 2000 feet is its passage over a large expanse of land or sea. Air from the Continent is cold, while air from the Atlantic is relatively warm. On the Atlantic, however, some polar effect is shown when the path of the air is followed back for two days or more. At 4000 and 10,000 feet the chief factor is now the north to south component of the air's path, while the land and sea effect is small. Trajectories show that it is the latitude of the air two days before or even longer that determines the temperature.—L. H. G. **Dines**: A simple electrical time-marking system for use with self-recording meteorological instruments. The simple system of synchronous electrical time-marking installed a few years ago at Valencia Observatory, Cahirciveen, Co. Kerry, is described. A central clock operating hourly and minute contacts in series closes an electrical circuit once an hour. The circuit includes electro-magnets acting on suitable portions of the recording mechanism of the self-recording instruments which it is desired to include in the scheme. By this means time marks are easily obtained to an accuracy of a second or less.

Linnean Society, June 19.—Dr. A. B. Rendle, president, in the chair.—C. E. **Salmon**: A hybrid between *Carex remota* and *C. divulsa*. This occurred near Mayfield, in Sussex, in one large clump with a quantity of *C. remota* and a little *C. divulsa*. It differs from *C. remota* by its more scabrous stem, only one (or at most two) bracts, spikelets male at the summit, or even wholly male, and in other particulars. *C. remota* × *divulsa* seems extremely uncommon and is perhaps new.—T. A. **Dymes**: The seed of *Orchis latifolia*. The seeds of the British Dactylorchids fall into two groups: (1) Maculatæ, and (2) Latifoliæ. A form, agreeing in other respects with *O. latifolia* L., the seeds of which are obviously pure, has been found. The seeds belong to group (2) Latifoliæ, and are very like those of *O. prætermissa* Druce, and it seems probable that the two forms are close allies of the same species.—J. H. **Priestley** and Miss Lorna I. **Scott**: Leaf and stem anatomy of *Tradescantia fluminensis*

Vell. Vascular development in the leaf is first basifugal and afterwards basipetal, and the backward development of the subsidiary veins through the leaf sheath is associated with the subsequent development of the system of peripheral bundles, which lie in the sclerenchyma very near the periphery of the adult stem. Thus the functional vascular supply to the leaf passes through two stages in the stem. In the young internode, communication is maintained by means of the medullary and perimedullary bundles; as the growing internode extends in length the xylem of these bundles is disorganised, but at this time the peripheral bundles are differentiated throughout the internode and become functional.—T. B. **Blow**: Charophyta collected during a recent visit to Madagascar. These plants are interesting by reason of their affording a possible means of preventing the spread of malaria by acting as larvicides. The country covered was the east coast line, where are great marshes and much water, and where malaria is rampant, the higher ground around the capital, Tananarive, where the climate is much healthier, the mountainous portions near Antsirabe, where mosquitoes scarcely exist, and the district of the great Lake Alaotra, which is probably the most malarious part of Madagascar. It was noticed in connexion with several species of Chara that, where they abounded, there were rarely any mosquito larvæ in the water. The species that seemed to keep the water quite free of mosquito larvæ were as follows: *Chara Zeylanica, C. gymnopitys, Nitella Roxburghii*, and some other species of Nitella probably new.

DUBLIN.

Royal Dublin Society, May 27.—Prof. E. A. Werner in the chair.—W. R. G. **Atkins**: Notes on the filtration and other errors in the determination of the hydrogen ion concentration of the soil. As a general rule, the effect of increasing or decreasing the soil to water proportion, within limits, does not alter the P_H value by as much as 0·1 for soils between P_H 6 and P_H 8. With more acid or more alkaline soils larger alterations are thus caused. For lightly buffered acid soils one part of soil to two parts of water seems a safe proportion to adopt; for other soils a one to five proportion is convenient and, apparently, trustworthy. The P_H value of some soil extracts is markedly modified by filtration, even when a first filtrate is rejected. Both untreated and acid-extracted filter-papers may reduce the acidity. The use of large volumes, about 160 c.c., of filtrate, and a filter appropriate to the soil, reduces these errors: where possible, cleaning by the centrifuge is desirable. The fibres of acid-extracted papers act towards indicators as if as acid as P_H 4·8, but washing was not found to render them less acid. Unextracted papers are at about P_H 7·0-7·6, and give up traces of alkali to distilled water. The indicator brom-cresol green is to be preferred to methyl red for the same P_H range.—J. L. **McWhinney**: The soil fauna of a permanent pasture. A census of the invertebrate fauna resident on the surface, and in the soil to a depth of nine inches, of a permanent pasture forming part of the experimental farm of the Albert Agricultural College, Glasnevin, Co. Dublin, reveals a considerably greater density of population than has been found by other workers elsewhere. If the soil be dried before the count is made, numbers of the smaller species may be overlooked.

EDINBURGH.

Royal Society, June 2.—Prof. F. O. Bower, president, in the chair.—D. A. **Allan**: The igneous geology of the Burntisland district. Penetrating the Lower Carboniferous rocks of this area is a group of eleven volcanic necks, one of which is recorded for the first time. An examination of the boulders in the agglomerate has failed to produce material younger in age than the surrounding rocks. The lava flows comprise olivine basalts of the Dalmeny and Hillhouse types, together with a pyroxene-rich variety now designated as being of the Kinghorn type. From a consideration of the variation of the lavas, it has been possible to establish upon broad lines a series of zones. The intrusions include olivine basalts, teschenites, olivine dolerites, olivine-free dolerites, and quartz dolerites, the last named being probably the latest in development.—Ada M. **Malcolm**: The magnetic quality of very pure nickel. A nickel bar was examined by the magnetometric method (*a*) in a horizontal position, (*b*) in a vertical position, with and without an additional stress of ½ kgm. weight—the magnetising fields being of very low order. With the same bar in the horizontal position, complete hysteresis cycles were made, the field being increased in one case step by step, and in the other being continuously varied. The constant values of the susceptibility (K) and the permeability (μ) were calculated: $K = 4{\cdot}17$ to $4{\cdot}20$; $\mu = 53{\cdot}53$ to $53{\cdot}77$. A circular coil of nickel wire was also used, and its saturation point determined by means of a ballistic galvanometer. The graph tended to become straight in the neighbourhood of a field of 100 gauss. The purity of the nickel was not less than 98·5 per cent.—Winifred J. **Smith**: The law of recurrence and decay of after-images. The sequence of colours observed, after exposing the eye to white light for a given period, can be represented graphically by the combined effect of three exponentially decaying periodic curves, representing the sensations of red, of blue, and of green. Differential equations were derived from the curves chosen to represent the experimental results. The form of these differential equations suggests two different physical analogies, one to the interaction of three condensing electric circuits, and one to the motion of elastically connected masses.—H. **Briggs**: Apparatus to facilitate the use of an oxygen-carbon dioxide mixture on the treatment of carbon monoxide poisoning. The orthodox treatment by means of oxygen of a case of carbon monoxide poisoning is not especially effective, being apt to bring about sub-normal breathing at a time when the reverse is needed. Henderson and Haggard, of Yale University, have developed the method of treatment by oxygen plus 5 per cent. of carbon dioxide, a mixture which has not the same disadvantage. It stimulates breathing from the moment of application, and reduces the chance of serious sequelæ. The mixture is now obtainable commercially in America under the name of "carbogen." As carbogen cannot yet be bought in Great Britain, it was necessary to devise an apparatus to make it. The liquid carbon dioxide in a large-sized "Sparklet" bulb can be discharged into an oxygen cylinder of 290 litres capacity, the cylinder being then charged with oxygen to the standard pressure of 120 atmospheres. The mixture so made contains 5 per cent. carbon dioxide.—R. S. **Vaidyanathaswamy**: On mixed determinants. This paper deals with the extended determinants, containing suffixes of two different kinds (the "signants" and "non-signants" of Rice), and leads up to the concept of "inert suffixes" of matricular invariants, and the concept of "extensional invariants." Some features of the determinant-theory advanced are: (1) a new account of the "decomposition" of a determinant into determinants of lower dimensions, as a quoted development by linkage of "suffixes"; (2) a systematic use of "one-dimensional determinants"

as the ultimate entities of determinant-theory; (3) a new and improved version of the theory of multiplication of determinants.

PARIS.

Academy of Sciences, June 16.—M. Guillaume Bigourdan in the chair.—Louis **Gentil**: The structure of the *Dorsale Tunisienne*.—Charles **Richet** and Mme. A. **Le Ber**: The relation between the time of action and the concentration of a sterilising substance (hydrogen peroxide). In sterilising a culture with an antiseptic two factors intervene, the concentration of the antiseptic and the period of time during which it is allowed to act. Results of measurements of the minimum sterilising dose of hydrogen peroxide are given for times varying between 3 minutes and 15 hours.—E. **Leclainche** and H. **Vallée**: Symptomatic anthrax and gas gangrene in cattle. Clinical and bacteriological studies of *B. septicus* and *B. chauvœi*, and their pathological and immunising effects on cattle and horses.—A. **Desgrez**, H. **Bierry**, and L. **Lescœur**: A mode of differentiation of sulphurous waters.—Ch. **Depéret** and L. **Mayet**: Reply to the observations of S. Stefanescu on the phylogeny of elephants.—Jean **Effront**: The absorbing power of vegetable pulps.—Paul **Vuilemin**: Anomalies of leaves caused by alloplasy.—**de Montessus de Ballore**: The unsymmetrical curves of Gauss.—V. **Illavaty**: Remark on the quasi-asymptotic curves of Bompiani.—J. A. **Schouten**: The conformal and projective connexions of Cartan and the general linear connexion of König.—R. H. **Germay**: Application of the method of successive approximations to a lemma of Weierstrass and to its generalisation.—Georges J. **Rémoundos**: Couples of functions which satisfy an algebraic equation.—A. **Bloch**: The theorems of M. Valiron on integral functions, and the theory of uniformisation.—R. **Gosse**: Explicit integrals of equations of the first class, $S = f(x, y, z, p, q)$, which admit an intermediate integral of the first order.—André **Metz**: Concerning the geometry of a disc turning in a Galilean system.—C. **Kolossoff**: The torsion of prisms having a right-angled triangle as base.—A. **Gros**: Finite bending of a circular ring compressed diametrically.—J. **Seigle**: Some observations relating to the effects of permanent torsions on steels.—Louis **Roy**: Electrodynamical and electromagnetic induction in continuous media in motion.—Y. **Rocard**: Extension of some results of the kinetic theory of gases.—G. **Athanasiu**: The distribution of energy in the mercury arc spectrum. Measurements were made on three groups of lines, using a spectrometer with a quartz optical system, and a thermocouple for reading the energy of the radiations. The mercury arc lamp was maintained with a current of 3·75 amperes, the voltage varied between 30 and 80 volts. It was found that the energy curves of lines belonging to the same series had the same general shape. The ratio between the intensities of two lines of the same series remained practically constant when the energy consumed by the arc lamp varied between 100 and 300 watts.—Jean **Lecomte**: Quantitative studies on the infra-red absorption spectra of organic substances. In the infra-red region the opacities of the different substituting groups are not additive.—A. **Dauvillier**: Spectrographic researches on the A. H. Compton effect. The Compton effect only appears in the case where the selective absorption is very small, and it is far from having the generality predicted by the theory.—Max and Michel **Polonovski**: The derivatives of eserine obtained by hydrogenation.—Léon **Guillet**: The influence of the velocity of cooling on the properties of commercial aluminium. The mechanical properties and the electrical resistance of aluminium are modified by the velocity of cooling, at least, if the percentage of silicon is a little high. The properties of commercial tempered aluminium do not sensibly change on keeping.—K. v. d. **Grinten**: Adsorption and cataphoresis. An application of the method of electric transport observed with the ultramicroscope.—Sir William J. **Pope** and F. G. **Mann**: 1.2.3 triaminopropane. Its preparation; formation of complex metallic derivatives. The method of preparation of this triamine given by Curtius and Hesse is tedious and not without danger. The new method involves the following steps: citric acid, acetone dicarboxylic acid, di-isonitroso-acetone, diaminoacetone, diacetyldiaminoacetoxine, 1.2.3 triaminopropane. The yields are good throughout, and with the base thus obtained the complex cobalt and rhodium compounds $[Co(NH_2 . CH_2 . CH(NH_2) . CH_2NH_2)_2]Cl_3$ and $[Rh(NH_2 . CH_2 . CH(NH_2) . CH_2NH_2)_2]Cl_2$ have been prepared. The stereo-chemical study of this new type of metallic complex is being carried out.—Marcel **Delépine**: The origin of fenchol in the reaction of Bouchardat and Lafont. Turpentine treated with either mineral acids or organic acids always gives a mixture of borneol and fenchol esters.—C. **Vournazos**: The formation of the bismuthamines.—H. **Gault** and Y. **Altchidjian**: The dissociation of hexadecene at high temperatures.—R. **Locquin** and L. **Leers**: The dehydration of some new pinacones. Starting with the pinacones $R(CH_3) . C(OH) . C(OH) . (CH_3)_2$, hydration by Meerwein's method yielded the ketones $R(CH_3)_2 . C . CO . CH_3$ (R being normal propyl, butyl, or amyl) with no indication of the presence of the isomeric $(CH_3)_3 . C . CO . R$. Ketones of the latter type were prepared by another method for the purpose of comparison.—E. **Raymond** and G. **Clot**: The acetyl index of fatty materials. The method proposed is based on the volume of methane produced by the action of magnesium methyl iodide in anisol solution on the dried fat, with correction for fatty acid present.—P. **Lebeau** and J. **Marmasse**: The quantity and nature of the gases evolved by solid combustibles under the action of heat and a vacuum: lignites.—L. **Cayeux**: The felspathic grits of the Hercynian Chain and the products of Permo-Triassic evaporation.—Gaston **Astre**: The tectonic units of the Sierras del Cadi, of Port del Compte and of some adjacent massifs (Catalanian Pyrenees).—M. de **Lamothe**: The tectonic evolution of the relief of the southern Vosges during the Quaternary, and solution of the problem of Noir-Gueux.—Ch. **Mourain**, E. **Salles**, and G. **Gibault**: The value and variations of the terrestrial field at Val-Joyeux, near Paris. Curves summarising results obtained with the self-recording apparatus installed at the Val-Joyeux Observatory, showing the annual variation of the terrestrial electric field as a function of the period of the year, and also of the time of day.—E. **Bauer**, A. **Danjon**, and Jean **Langevin**: Crepuscular phenomena on Mont Blanc.—W. **Kopaczewski** and M. **Bem**: The electrical conductivity of mineral waters as a means of their control.—H. **Colin**: The sugar beet and the forage beet.—Mme. B. **Brilliant**: The water content in leaves and assimilating power.—Fernando de **Buen**: The biology of the sardine in Galicia (Spain).—Louis **Fage**: A new type of Mysidacea in the subterranean waters of the island of Zanzibar.—André **Leroy**: The transparency of the shells of hen's eggs, and the modifications which it undergoes with time.—Ch. **Pérard**: Researches on the coccidia and coccidoses of the rabbit.—T. **Mutermilch**: The nature of the heterologue hæmolysins (Forssmann).—N. **Ishimori** and T. **Metalnikov**: The immunisation of the caterpillar of *Galleria melonella* by non-specific substances.

WASHINGTON, D.C.

National Academy of Sciences (Proc. Vol. 10, No. 5, May).—E. **Tomanek** and E. B. **Wilson**: Is pneumonia increasing? Statistics have been gathered of all forms of pneumonia in the United States registration area for the period 1900–1920. Making due allowances for the increase of registration area during that period, for the changed standard of life and economic conditions, and for difficulties of diagnosis, it is inferred that the disease is neither increasing nor decreasing.—G. A. **Miller**: Prime power substitution groups whose conjugate cycles are commutative.—R. L. **Moore**: (1) An extension of the theorem that no countable point set is perfect. (2) Concerning the prime parts of certain continua which separate the plane.—J. R. **Kline**: Concerning the division of the plane by continua.—F. B. **Sumner**: The partial genetic independence in size of the various parts of the body. Castle's figures for the correlation between total size and the size of individual organs or members are calculated from data from a "mixed population." Much lower correlations are obtained if sets of calculations are confined to a single race.—W. E. **Castle**: Are the various parts of the body genetically independent in size? A reply to the preceding paper. The calculations were based on a "mixed population" deliberately. It was sought to discover whether with change in general body size through genetic (not environmental) agencies there was a corresponding change in different parts of the body; hence it was desirable to start with differences in body size as great as possible.—L. L. **Woodruff** and E. L. **Moore**: On the longevity of *Spathidium spathula* without endomixis or conjugation. This organism was cultured by daily isolation in standard beef extract for 444 days, after which the animals suddenly appeared abnormal and died. The graph giving the average daily rate of division of the four lines of culture used shows only such fluctuations as may readily be accounted for by external factors. Pedigree cultures of *S. spathula* have shown progressive lengthening of life without endomixis or conjugation, and it is now considered that the organism can reproduce indefinitely in this way, given suitable environment.—D. L. **Webster**: A possible explanation of tertiary line spectra in X-rays. Objection is raised to the hypothesis of Clark and Duane on the grounds that the energy of the tertiary beam would be very small and that the narrow peak observed in the ionisation curve cannot result from reduction by filtering on emergence from the radiator of a continuous spectrum. It appears more probable that the atoms ejecting the photo-electrons are the source of the radiations. Data from the spectra of thin targets are in general agreement with this hypothesis.—G. L. **Clark** and W. **Duane**: On the theory of the tertiary radiation produced by impacts of photo-electrons. The short wave-length limits and the angles corresponding to them, calculated from Webster's theory, are not in accord with experimental and theoretical results obtained by Clark and Duane except for elements of low atomic number. This is to be expected since the difference between the theories resolves itself into a difference, which increases rapidly with the atomic number of the element, between a critical absorption frequency and that of a given emission line. Clark and Duane's theory also offers an explanation of the radiation found by de Broglie on the long wave-length side of radiations from a tungsten-carbon target.—S. K. **Allison** and W. **Duane**: Absorption measurements of certain changes in the average wave-length of tertiary X-rays. The "hump" of tertiary radiation in Clark and Duane's experiments shifts towar longer wave-length with increase in the angle betwe the primary and secondary X-rays. Using t secondary radiation of maximum intensity a employing a polished silver plate as seconda radiator, the effects of tellurium, antimony a iodine screens were investigated. An apprecial quantity of radiation shifts over to longer wa lengths at angles greater than 40°.—I. S. **Bow** and R. A. **Millikan**: The series spectra of the stripp boron atom (B III.). All the lines which, fr theoretical considerations, can be expected in a strength from a boron atom deprived of all valer electrons, have been identified. Lines hitherto r identified or now discovered occur at λλ 4499·0 2077·79 A; another line at 677·1 A is shown to doublet with a separation of 0·15 A (correct to least 0·01 A) or in frequencies, of 32·7 cm.$^{-1}$. T line at 758·5 A is the first term of the sharp ser of B III.

Applied Chemistry in Peace and War.

In a recent issue of the official organ of the Society of Dyers and Colourists,[1] Prof. Gardner reviews impartially and judicially the present position of the British dyestuffs industry, more especially with regard to recent negotiations between the British Dyestuffs Corporation Ltd. (B.D.C.) and the Interessen-Gemeinschaft (I.G.). His article, which is written in non-technical language, should be read by all wishing to obtain a clear perspective of the dyestuffs problem in its national aspects.

It is essential in considering the merits and demerits of the proposed agreement to differentiate clearly between the British dyestuff industry and the B.D.C., a distinction which is daily becoming more pronounced in proportion as the independent dyemakers gain an increasing amount of the home trade in colours. An agreement which is mutually advantageous to the I.G. and the B.D.C. may nevertheless be ruinous to the British competitors of the latter organisation. A criticism frequently made against the recent report of the Dyestuffs Development Committee of the Board of Trade is, that this document emphasises the great technical advances made since the War by British colour chemists, and at the same time urges the need for a continuance of the protection afforded to the industry by the Dyestuffs Act. The two points of view are, however, not inconsistent.

The enormous improvement in manufacturing capacity cannot be gainsaid. It may be recalled that prior to the War, 80 per cent. of British requirements for dyes came from abroad, and principally from Germany; at present "something over 80 per cent." of our home needs are supplied by British makers. It is, however, to secure the remaining 16 per cent. that the directors of the B.D.C. are striving for an arrangement with the great German combine. It is argued, Why should we expend money on research when the results are ours for the asking? Not being chemists, the directorate forgets that there is no finality in chemical industry, and that even now investigations are on foot which may render obsolete many of these precious dyes and also the majority of the commoner ones. To ensure steady growth, the still infantile industry needs protection not only from competition outside but also from apathy and lack of knowledge within the nation.

At the same time, it should be conceded that, so far as the interests of his shareholders are concerned, the chairman of the B.D.C. has done a great work in internal reorganisation and retrenchment, and also, in

[1] W. M. Gardner, "The British Dyestuffs Industry," Journal of the Society of Dyers and Colourists, vol. 40, No. 6, June 1924. (Bradford: Pearl Assurance Buildings, Market Street, 1924.) 5s.

view of the possible repeal of the Dyestuffs Act, he has made a very good bargain with a foreign competitor against whom the home industry would be heavily handicapped if the existing restriction on foreign importation were removed.

While these acute discussions are in progress in Great Britain, five lectures delivered by Prof. Haber during the last four years, and recently published,[2] have the sombre significance of the writing on the wall, for the text of his discourses may be taken to be the national necessity of a self-contained chemical industry vital to the public welfare either in peace or war. As the recipient of a Nobel Prize, the lecturer naturally dealt with the more peaceful attributes of the industrial synthesis of ammonia from its elements. But the warlike aspects of chemical science are displayed in the address on "Chemistry in War," delivered to the officers of the Ministry of National Defence (1920), and in the lecture on "The History of Gas Warfare," given last October before the Parliamentary research committee of the German Reichstag. In the former discourse Haber refers to the larger problems of munitions which arose in Germany on the prolongation of the War, and also on the special requirements for chemical warfare. He compares favourably the comparatively humane nature of the casualties inflicted by chemical means with the ghastly and disfiguring wounds produced by flying shrapnel and the other older weapons, and points out that, in spite of the Washington Conference, the fervent wish expressed in England, as in America, for the establishment of an independent chemical industry is due to a recognition of the importance of this trade in the production of chemical munitions of war.

In the lecture to the Reichstag representatives, Prof. Haber traces the development of chemical warfare both before and since the surprise attack with chlorine made by the German army at Langemark on April 22, 1915. He concludes by asserting that the moral indignation displayed in the Entente press during the War was directed principally against German gas warfare, but not against the employment of similar weapons by the Allies.

It is doubtful whether the proposed agreement between the B.D.C. and the I.G. will restrict secret preparations for gas warfare being made by any nation holding a predominant and self-contained position as regards the chemical arts. Our path of safety is to encourage to the utmost the development of research and industrial expansion in an independent national dye industry. G. T. M.

Sir Archibald Geikie.

A Long Life's Work: an Autobiography. By Sir Archibald Geikie. Pp. xii+426. (London: Macmillan and Co., Ltd., 1924.) 18*s.* net.

FROM time to time Sir Archibald Geikie has interested his numerous readers by writing sketches or reminiscences of incidents in his long and busy life. In the volume now before us he has set out in orderly sequence the principal events of his career from early boyhood to a well-earned period of rest. Advancing years may have curtailed his activities, but his memories of friendly intercourse with many distinguished men in all parts of the world, of the almost innumerable functions in which he has taken a prominent part, and the charm of the literary style in which he tells his experiences, remain as fresh as ever.

Born in 1835, Geikie's earliest reminiscences relate to incidents which to many of us seem to belong to ancient history, as, for example, the gathering of the Elders at the Disruption of the Kirk of Scotland, when black coats swarmed like hiving bees in and out of St. Andrew's Church, or the opening of the first railway in Scotland. But interest centres chiefly on the early proclivities of the boy himself, inasmuch as he was destined to become a leader in geology, a noted man of letters and a distinguished public servant.

At the Edinburgh High School, Geikie acquired an appreciation of the Latin classics which has been a joy to him all his life, but a love of Nature was evidenced by a passion for collecting butterflies. It was while so engaged in a limestone-quarry that he first found a fossil. Enthusiastically he broke up block after block, disclosing delicately preserved plants, and realising, not without awe, that he was bringing to the light organisms that had never before been seen by human eyes. Thenceforward the rocks and their fossils became increasingly the subject of his thoughts. Through this incident he became acquainted with Robert Chambers, author (as it appeared later on) of "Vestiges of the Natural History of Creation." He read every book on geology he could lay hands on, but in the "Old Red Sandstone" of Hugh Miller found a greater stimulus than in any other, not so much from the information it supplied as from its revelation of the enthusiasm of a true lover of Nature. From the consideration he received at the age of seventeen from such men as Logan, David Forbes, and Sorby, it may be inferred that he had already shown unusual promise as a geologist.

The time had come, however, for choosing a profession, and to his parents, as to so many others before and since, it appeared that though geology might be

a pleasant pastime, it could scarcely provide a living. They decided therefore to put young Geikie into a bank after two years' instruction in law in the office of a Writer to the Signet. The work proved to be "unspeakably dull," and the two years' training was never completed.

During a holiday in London Geikie returned to his old love. He passed many happy and profitable hours in the galleries of the newly established Geological Museum in Jermyn Street, and about this time (1853) first heard of the Geological Survey, a branch of the public service which had been initiated by De la Beche some ten years before. An interview with Sir Andrew Ramsay, at that time local director, and a walk taken over Arthur's Seat at Ramsay's invitation (issued, as we may suppose, for the purpose of forming an opinion of the young geologist's capability), led to a suggestion that a post on the survey might be found. In the interval of waiting he wasted no time. Some geological work in Skye formed the basis of a communication to the Royal Physical Society of Edinburgh in 1854, his first appearance before a learned society. Determined to continue his literary studies, he matriculated at the University of Edinburgh as a student of the humanities, and though prevented by domestic circumstances from completing the course, he became one of the best scholars of his year and the best writer of English prose and verse. In 1855 he obtained a post on the Geological Survey, and commenced his long career as a professional geologist. Let it be well taken to heart that he had equipped himself not only as a geologist, but also as a scholar and man of letters.

In the next few pages Geikie describes the work of a field-geologist, the simple accoutrement required, and the difficulty country people felt in understanding how he could tell what lay below the surface of the ground without digging. The work was arduous, and according to official regulations occupied nine hours a day, in practice probably much more. He found time and energy, nevertheless, to pursue his classical studies, and even enlivened long tramps home by recitations from his favourite poems. "I look back," he says, "on this period of my life as perhaps the most studious and certainly one of the most delightful that I have been privileged to enjoy." New discoveries in geology quickly followed, notwithstanding MacCulloch's vainglorious boast that he had left nothing in the geology of Scotland that could not have been effected by a surveyor's drudge or a Scottish quarryman. A fossiliferous shale was detected under massive sheets of Old Red Sandstone lava, but the origin and age of igneous rocks began to take first place in Geikie's attentions. In touching upon such questions he conveys his information in language which is intelligible to non-scientific readers; modern scientific technicalities find no place in these pages, when good English serves. For some time Geikie was the sole representative of the Geological Survey in Scotland. On him alone lay the responsibility of mapping a region extending into several counties and calling for much sagacity in dealing with new problems.

In 1860, owing to the death of Prof. George Wilson, who had had it in hand, it fell to Geikie to complete the "Life of Edward Forbes." Some hesitation was felt in entrusting the work to so young a man, but the book was completed and published in 1861, forming the first of a number of charming biographies from the same pen. In the autumn of 1860, Geikie accompanied Murchison on a tour through the Highlands, and though the secret of the Highlands was not yet to be told, his accounts of the hospitalities extended by the many large landowners with whom Murchison was acquainted, make good reading. In the winter, Ramsay having been taken ill, Geikie was called upon to take over the lectures at the Royal School of Mines and the popular geological addresses to working men in the theatre of the Jermyn Street museum. These addresses were delivered by the most eminent men of the day on their respective subjects and were attended by crowded and intelligent audiences. I have myself seen the theatre full of working men listening spellbound to an exposition by Huxley of the elements of biology.

The relics of the Glacial Period, during which a large part of the British Isles was overridden by ice-sheets, now began to claim Geikie's attention. Boulder clays, sands and gravels, collectively known as "glacial drift," were spread over the country during this period in such quantity as to dominate the soil and often completely to mask the characters of the underlying "solid" formations. A holiday spent in quest of glacial drift led to a communication to the Geological Society of Glasgow in which Geikie reviewed the sequence of events in Scotland and showed the boulder-clay to be the product of an ice-sheet, and not, as was stoutly maintained by many, of floating ice. He obtained confirmation of this view by an exploration of northern Norway.

By this time Geikie's intimate knowledge of a large part of his native country, his appreciation of a landscape, and the geological training by which he was enabled to interpret the significance of the features of the ground, impelled him to the writing of "The Scenery of Scotland." The book, though in direct antagonism to Murchison's cataclysmic opinions, was dedicated to him. The compliment was accepted without demur.

In 1867 a separate branch of the Geological Survey was constituted for Scotland and Geikie was appointed

director. Suitable men for the posts on the new branch were scarce, and among the candidates one at least, who afterwards achieved a great reputation as a geologist, and was in fact an able algebraist, failed to add up correctly against time long columns of pounds, shillings, and pence, a test of the capability of a field-geologist which was insisted on then and for many years afterwards by the Civil Service Commissioners. Friendships with many eminent literary and scientific men continued to ripen. Alexander Macmillan was one of the earliest and most constant. Another old friend, Poulett-Scrope, a high authority on volcanic problems, being desirous that the volcanic regions of southern Italy should be examined by a competent geologist, contributed two hundred pounds for the expenses and suggested to Geikie that he should undertake the examination. The offer was accepted, but a severe fever, developed at Lipari, put an end to the project.

Provision for a chair of geology in the University of Edinburgh having been made by Murchison in his will, he desired to nominate Geikie as the first professor. The Home Office objected to this as an interference with the prerogative of the Crown, and the Science and Art Department objected to two posts being held simultaneously by the same man. The objections were, however, overcome, mainly through the influence of Lyon Playfair, Member of Parliament for the University, and Geikie was appointed in 1871. In this same year he married and travelled to the south of France to visit his wife's relatives, witnessing on the way some of the horrors of a successful Prussian invasion. He was summoned back to the deathbed of his old chief and friend, Sir Roderick Murchison.

The creation of a school of geology in a poorly endowed University was beset with difficulties; lecture-rooms were inadequate, and rocks and fossils were lacking. The exceptional advantages for field-work offered by the country round Edinburgh were therefore utilised to the full. The field took the place of a lecture-room, and Nature supplied the specimens. In his second year the professor lectured to the Ladies' Educational Association and conducted geological excursions of ladies. Mixed classes, however, were not yet tolerated, and the male students were returned to their homes before the ladies appeared, a mistake in the opinion of the good lady who kept the inn where they stayed. Later, he lectured to the lunatics at the Morningside Asylum, and, by the help of an official, to the inmates of a Deaf and Dumb Institution.

These varied activities were not allowed to interfere with literary work. The third edition of Jukes's "Student's Manual of Geology" was completed by Geikie in 1871; in 1873 two science primers were written, and "The Life of Murchison" was in hand. In the same year, also, obituary notices of two old and valued friends, Logan and Lyell, were gratefully undertaken. At this time, what was perhaps the most onerous task in a busy life began to occupy his mind, namely, the preparation of an advanced text-book of geology. This work, a monument of research, of matured judgments and of lucid statement, was published in 1882. It is interesting to hear that the author of such a work found the writing of the little primers the most difficult task he had ever undertaken. The preparation of a classic memoir on the Old Red Sandstone, and a study of the weathering of marble and other rocks, as evidenced by tombstones, helped to consume what surplus energy was left after the performance of official duties.

An engagement to lecture to the Lowell Institution in Boston in 1879 led to an extended tour in the United States, in the course of which the Yellowstone Park and Salt Lake City were visited. While at Boston Geikie dined at Lowell's house and sat between Longfellow and Oliver W. Holmes. The poet's face "always beamed with a kindly smile," but to talk to him proved difficult.

In 1882 Geikie succeeded Ramsay as Director General of the Geological Survey and resigned his Edinburgh professorship. His new duties included supervision of the Scottish and Irish branches, the latter no sinecure, when one member of the staff, still well remembered, was on the warpath. Yet now as ever, time was found for literary work. The text-book was not yet published, and "Geological Sketches at Home and Abroad" was in preparation. At the same time he was prosecuting his studies of British Tertiary volcanic history, the results of which were published by the Royal Society of Edinburgh and were afterwards embodied in "Ancient Volcanoes of Great Britain."

The next few years saw no relaxation in this strenuous life. He was elected foreign secretary of the Royal Society in 1889, but undertook a more onerous task as president of the Geological Society in 1891–92. Presidentship of the British Association followed soon after, and among a shower of press clippings with which the occupant of such a post is bombarded, was one from a phrenological journal to the effect that the "organisation of this gentleman is most favourable for almost any sphere of life." The prophet was on safe ground, for, in addition to the posts already mentioned, Geikie was a member of the Royal Commission on Water Supply and of the Departmental Committee on the Ordnance Survey.

Among much other literary work now in hand was a biography of Sir Andrew Ramsay, the late Director-

General. In lighter vein were the dinners of the Literary Club. At these monthly gatherings Geikie met many distinguished men of letters and retailed the latest good stories from Scotland. The appearance of some of these in *Punch* puzzled him for a time, but he eventually detected the route by which they had travelled. A few years later in "Scottish Reminiscences" he published a selection of (but not all) his experiences of Scottish manners, customs and speech.

A visit was paid to Paris in 1891 to attend the centenary of the Institut de France. The guests were received at an evening function by M. Poincaré, then in his thirty-fifth year. Six years afterwards Geikie received through the French Embassy a beautiful specimen of Sèvres ware, but it was not until some months had elapsed that the unexpected gift was explained. Prof. Fouqué and M. Michel Lévy had moved their Government to accord Geikie the decoration of the Legion of Honour. But the French Ambassador pointed out that the British Government did not approve of the acceptance of foreign decorations by British subjects. The china had therefore been sent as a public mark of esteem, with an expression of keen regret that the British Government should be so exclusive. However, sixteen years later the Cross of the Legion of Honour reached its destination.

The International Geological Congress met every third year before the War, and in 1897 assembled at St. Petersburg. There Geikie was presented with other delegates to the Czar and Czarina and saw a charming phase of Russian home life in the country palace of the Dukes George and Michel of Mecklenburg.

The long period of service upon the Geological Survey was now drawing to a close. In the view of the Treasury, the service itself was of a temporary character and would cease to exist when a geological map of the British Isles on the scale of one inch to the mile had been completed. In such circumstances there had been a tendency to shelve questions relating to promotion, salaries and other matters, about which much dissatisfaction had arisen. This led to a request from the staff for a full inquiry, and eventually to the appointment of a strong committee, on which Government Departments, geological and mining interests were adequately represented. The recommendations made by the Committee were eminently practical and satisfactory. "It was to me," Geikie writes, "a great satisfaction to leave the service with the prospect that these much-needed reforms would be carried out." He retired in 1901 after a service of forty-four years and four months.

Abrupt severance from official duties is apt to leave a man at a loose end, but it was far otherwise with Geikie. Some Survey memoirs were still in hand, and various scientific societies made claims upon his time. Attendance at the first meeting of the International Association of Academies took him to Paris, and at the 450th anniversary of the University of Glasgow he was one of the recipients of the honorary degree of LL.D. In the winter of 1902–3 he attended meetings of the Reale Accademia dei Lincei, of which he was a foreign member, unaware that he was thereby earning a small fee for each attendance. In 1903, at the ninth meeting of the International Geological Congress, in Vienna, he renewed intercourse with his old friend Suess and many others. In this year also he was elected one of the general secretaries of the Royal Society, a post which involves much work in connexion with the numerous activities of the Society. Outside the ordinary routine was the making of arrangements in London for the second meeting of the International Association of Academies. The functions provided for the entertainment of the guests included a garden-party at Windsor Castle, when the members were received by King Edward and Queen Alexandra. The first centenary of the Geological Society was celebrated in 1907. It being felt that the presidential chair should be filled on such an occasion by a geologist of outstanding reputation, Geikie, though he had already been president, was asked to allow himself to be nominated. The celebration led to what was probably as distinguished an assemblage of geologists from all parts of the world as had ever met.

In 1908, on the retirement of Lord Rayleigh, the Council of the Royal Society nominated Geikie as his successor to the presidential chair. The many duties which are attached to the post, both within the Society's rooms and outside, made serious inroads upon his time, but gave him the opportunity of devoting his energies more strenuously than ever to the welfare of the Society. The most outstanding incident during his presidentship was the celebration of the 250th anniversary in 1912. Men distinguished in every branch of science attended from all parts of the world. After a short service in Westminster Abbey, the delegates handed the addresses with which they had been entrusted to the president in the Society's Library. In the evening a banquet was held in the Guildhall, at which the toast of the Royal Society was given by the Prime Minister and responded to by the president. An unpremeditated toast was added to the list during dinner, that of Prince Lichnowsky, the newly appointed German Ambassador. In his reply he said, "Never between England and Germany have there been more intimate and more sincere relations than at present. Both countries are working side by side in the same cause of maintaining European peace." It appears to have been a fact that the preparations for the War, then

being made by the higher powers in Germany, were not known to the German Ambassador. Two notable volumes were prepared at Geikie's instance in readiness for the celebration; one an enlarged edition of the Society's "Record," the other a facsimile reproduction of the Charter Book containing the original signature of Charles II., followed by the signatures of all fellows from the commencement, "a collection of autographs probably without an equal, as representative of the science and culture of Europe during the period which it embraces."

At this time the British Academy came into existence and was soon followed by the Classical Association. As president of the latter Geikie chose for the subject of his address the evidence in Latin literature of an appreciation of Nature by the Romans. The subject proved so fascinating that he pursued it later on both at home and amidst landscapes that must have been familiar to some of the Roman poets. The writing of the book, "The Love of Nature among the Romans," served, so far as anything could, to distract his thoughts from the tragedy of the death of his only son, a young man of brilliant promise.

From 1914 Geikie's time has been spent chiefly at his country home near Haslemere, and though not so active as he once was, there has been little relaxation in his industry. In 1920 he was elected as chairman of the Royal Commission of Inquiry into the University of Dublin. "The Annals of the Royal Society Club" was written during these years of retirement, and now has been followed by the fascinating volume to which this notice relates. It was during this period of quiet retreat, on the last day of 1913, that a special messenger brought the intimation that the King had conferred upon Geikie the Order of Merit. He had already been made K.C.B. in 1907. Space does not admit of the enumeration of the academic honours conferred upon him.

I cannot conclude more fittingly than in the words used by Walter H. Page, at the time American Ambassador. In a letter to Geikie on his birthday, which he had learnt was the same day as that of the President of the United States, he wrote, "You also are entitled to great thanks for being born into a world that you have made wiser and merrier by your presence and labour."

A. STRAHAN.

A Biological Study of Radiation.

Radium, X-rays and the Living Cell: with Physical Introduction. By Hector A. Colwell and Prof. Sidney Russ. Second edition, revised. Pp. xi+365 +3 plates. (London: G. Bell and Sons, Ltd., 1924.) 21*s.* net.

THE second edition of this book, which was first published nine years ago, brings the experimental biological study of the effects of radiations up-to-date; it includes a new chapter which summarises the action of rays on living structures, and discusses the theories put forward to explain these actions.

The authors are, rightly, cautious in discussing "Laws." Their subject is a new one, and it is only recently that the nature of X- and gamma rays has been settled and their place in the electromagnetic spectrum charted.

How do X-ray exposures cure tuberculous glands? By killing the tubercle bacilli? In a test-tube, X-rays can kill tubercle bacilli, but it takes a big dose—so big that no human tissues could live through the bombardment. How then does a moderate dose cure the patient? Clearly it is the human body that achieves the cure; the tissues react to the radiation, and kill and rid themselves of the intruding bacilli, weakened by the radiation. Many factors may be at work. The action of the X-rays may be selective, weakening the bacilli but weakening the tissue cells less, or actually stimulating the tissue cells to increased activity.

Clearly there are countless problems for experimental solution. The conclusions so far reached are valuable but (as the authors point out) they are still very incomplete, inconclusive, and even contradictory.

Of chief interest is the bearing of these researches on the treatment of cancerous growth. Stated briefly the conclusions are: Some growths can be abolished and an apparent cure obtained. Others can be reduced in size, with temporary relief, only to take on new activity which defies control by radiation. Even the "cures" are only too commonly illusory. The disease breaks out again in the same place or elsewhere and becomes disseminated. We seem to be no nearer the "cure" for cancer. But we need not despair, nay, we dare not. Although a cure may never be found, there is great hope of our learning how to prevent cancer. We are now certain that cancer is not a disease which springs upon us mysteriously, and strikes us down "like a bolt from the blue." It is the last phase of a chronic disease that affects our tissues, makes them unsound, and deprives them of their powers of resistance.

Certain races live a natural life in the open air engaged in active agricultural pursuits, and eating the natural "live" foods of Nature (grains, nuts, milk, eggs, fruits, and uncooked vegetables). These races are immune from the disorders of digestion so rife in civilised lands. They do not suffer from dyspepsia, gastric and duodenal ulcer, gall stones, appendicitis and colitis, and they live to a good age without falling victims to cancer. Contrast their state with that of dwellers in civilised towns. Their life is largely indoors and sedentary, their food and drink almost entirely "dead" food; it is frozen for long periods, or boiled and canned, or impregnated with chemicals, such as

borax, sodium salicylate, and saltpetre. Even the fresh foods that reach the consumer un-killed and undefiled, pass through the kitchen, and are there deprived of their living properties, and worked up into appetising dishes. "Hunger is the best sauce," but the life that is forced upon civilised races deprives them of this relish. To make matters worse, sugar (sweetmeats and chocolates) are eaten in great quantity. The consequence is that the digestive system fails; constipation and intestinal stagnation occur; the overfilled stomach and intestines drop and become kinked; their stagnant contents decompose and poison the system. Not only the stomach and intestines, but also every tissue of the body is poisoned and loses its power of resistance. Sooner or later a stage is reached when some part gives way, when we have another case of gastric ulcer or appendicitis, and the surgeon is called in to remove the part that has "rotted." If the surgeon is an observer, he notices that the rot is general and is not confined to the appendix, gall bladder, or gastric ulcer which he is removing.

A person whose tissues are in this state is certainly on the road to cancer, and little lasting good can come of an attempt to cure him by local radiation. He must "clean himself up"; then Nature will have a chance to aid him in his fight for life. The great good that may come from the experimental researches described in this book is that it may teach us Nature's method of ridding itself of morbid growths. The new edition is of immense interest to all who are engaged in the study of tumour growth.

Our Bookshelf.

A Practical Handbook of British Birds. Edited by H. F. Witherby. 2 vols. Vol. 1. Pp. 532+xvi. Vol. 2. Pp. 960+xii. (London: H. F. and G. Witherby, 1919–1924.) 4*l.* 10*s.* net.

THIS important work, which has been appearing in parts since 1919, is now complete, and the corrections and additions in the last part bring the whole up-to-date. The bound book is available in alternative forms, and of these the thin paper edition makes two volumes of little more than pocket size. It is thus a handbook in a real sense, but at the same time the quality of its contents fully entitles it to a worthy place on the library shelf with larger works of reference.

The object aimed at has been to give in a small space and in systematic form all the most important information about the external characters of British birds, their distribution and migration, their breeding habits, nests and eggs, their song and their food. This has been very successfully achieved by the authors responsible for the various subjects. The numerous illustrations, many of them in colour, are admirable from the point of view of practical utility as aids to identification. There are also useful key tables to the distinguishing characters of the different systematic groups.

The book is, however, more than a carefully compiled and well edited work of reference. It represents, indeed, much original investigation, the results of which are presented for the first time. This refers particularly to the descriptions of plumage, most of them by the editor himself, which constitute the most important part of the work. These descriptions have been based upon new examinations of large series of specimens, including those in the British Museum and in Lord Rothschild's large collection, and they take full account of all differences of sex and age and of all seasonal changes: the different geographical races or sub-species are separately treated. The method is consistently followed in this respect, and in a few cases, from their nature unimportant in British ornithology, a phase is frankly mentioned as "not examined." A great labour has obviously been performed, and as a result we have much valuable information not previously available, and a high trustworthy standard throughout.

The treatment of the other subjects is less detailed but quite adequate for the purpose, the limits observed being those proper to a condensed work of reference. The contributors, other than the editor, are Dr. Ernst Hartert, Miss A. C. Jackson (Mrs. Meinertzhagen), the Rev. F. C. R. Jourdain, Mr. C. Oldham, and Dr. N. F. Ticehurst.

This "Practical Handbook," then, in addition to containing important new contributions to ornithology, seems to us to be the most useful systematic text-book of British birds that can be placed in the hands of the serious student of the subject. It undoubtedly takes its place as a standard work.

The Year-Book of the Scientific and Learned Societies of Great Britain and Ireland: a Record of the Work done in Science, Literature, and Art during the Session 1922–1923 by numerous Societies and Government Institutions. Compiled from Official Sources. Fortieth Annual Issue. Pp. vii+389. (London: C. Griffin and Co., Ltd., 1923.) 15*s.* net.

WE are glad to be able to extend a welcome once more to this valuable handbook, which has now reached its fortieth anniversary. The publishers are to be congratulated on the courage and persistence with which they have issued year by year a volume so useful to all who would keep in touch with scientific developments and at the same time a book necessarily of limited circulation. The volume is divided into the customary fourteen sections, in each of which related societies are grouped. The classification this implies is a difficult problem, but we have little fault to find with the present arrangement; the Institute of Physics would appear more appropriately in the section given to astronomy, mathematics, and physics than in its present place under "Science Generally." The very full index, however, will generally obviate any difficulty which may arise in this way.

For those who are not familiar with the handbook, it is desirable to say that it gives full particulars of the scientific and learned societies of the British Isles, their officers, addresses, meetings, conditions of membership, publications, and, in many cases, the titles of the papers presented and lectures during the year

1922–23. There are also included accounts from Government institutions, such as the National Physical Laboratory, the Royal Observatory, Greenwich, and so on. In some few entries, telephone numbers and telegraphic addresses are also given; this might usefully be extended to all the societies which are served by telephone. We also think that a complete list of the various Research Associations, together with separate entries in their appropriate sections, would be valuable, while other omissions we have noted are the Institution of Chemical Engineers, the Eugenics Education Society, and the Institution of Welding Engineers.

The information provided by the handbook is furnished by officials of the societies concerned, and we must add our thanks to those of the publishers for making the volume possible. No doubt it is by a slip that the new address of the Institution of Automobile Engineers from August last has not been inserted.

Our criticism must not be taken as disparaging. In no other volume, we believe, is similar information brought together, and our suggestions are made in order that the next issue may give us cause for still more gratitude to the publishers and all concerned in issuing the handbook.

Canned Foods in Relation to Health. (Milroy Lectures, 1923.) By Dr. William G. Savage. (Cambridge Public Health Series.) Pp. vii+146. (Cambridge: At the University Press, 1923.) 8*s.* 6*d.* net.

THIS book consists of the author's "Milroy Lectures," delivered in 1923, with some amplification. The canning industry is a very important one in the United States and South America, and in the overseas Dominions. Though the industry is small in Great Britain, large quantities of canned foods are imported and consumed here. Thus in 1921 some 22,500 tons of canned meat alone (and much larger quantities of salmon and fruit) were retained in Great Britain.

Apart from the magnitude of the industry, there are special reasons why this class of food-stuffs needs supervision additional to that exercised over food generally. The most important of these is that the use of unsound constituents is less easily detectable than in the case of ordinary foods. Dr. Savage has examined various methods of manufacture, and pays a high tribute to the work done by the National Canners' Association (U.S.A.) in the improvement of the products of its members. But he finds that the control exercised over canned foods at the port of entry leaves much to be desired, and that better and more uniform methods are required for the disposal of the contents of rejected tins. Dr. Savage also urges that the date of preparation, together with a code mark for identification, should be stamped on all tins. The important subject of the causation of disease by canned foods is dealt with at length by Dr. Savage, and he comes to the comforting conclusion that canned foods as a whole are safer than fresh foods.

The book contains a very complete summary of this important subject, and concludes with appendices on the principles involved in the process of canning, and on the laboratory methods for the examination of canned foods, and with a selected bibliography of the subject.

Invertebrate Zoology. By Prof. Harley Jones van Cleave. (McGraw-Hill Agricultural and Biological Publications.) Pp. xvi+259. (London: McGraw-Hill Publishing Co., Ltd., 1924.) 15*s.* net.

IN this volume the author "has endeavoured to collate materials which will serve as a class-room text and reference work," assuming that the student has already had an introductory course in zoology. The attempt to compress an account of the invertebrates into 240 pages is, in our opinion, scarcely successful, for it has compelled the author to deal so summarily with many of the subjects and of the classes that the accounts are too short and inadequate to be of real value; *e.g.*, endomixis is dealt with in about eight lines, and the student can form little idea of the process from a perusal of this brief statement. It would have been better, we think, to omit reference to a number of the more difficult groups, *e.g.*, Phoronida (the account of which occupies about eight lines), and deal more fully with other groups. Some of the references to protozoa require revision; *e.g.*, that *Piroplasma hominis* is the causal agent of Rocky Mountain fever, and the use of "hæmogregarines" as synonymous with Babesia is incorrect. If a cyst of *E. histolytica* is to be illustrated at all, a figure better than Fig. 24 should have been provided. We can only conclude that in a course in which such a compressed account of invertebrates is used, it is intended that much of the information on any given group will be acquired in the laboratory, the text-book serving as a brief summary for reference.

The Diseases of the Breast. By Willmott H. Evans. Pp. xii+495+102 plates. (London: The University of London Press, Ltd., 1923.) 27*s.* 6*d.* net.

THE subject of diseases of the breast is one which presents many problems to the clinician, the pathologist, and the surgeon. Mr. Willmott Evans endeavours to sum up the present views on the subject and draws on his own experience to express opinions on controversial points. His book is certainly very complete, covering anatomy, physiology, clinical examination, pathology, and treatment down to the last detail. With regard to the disputed subject of dissemination of carcinoma, Mr. Evans has no hesitation in accepting the theory of permeation described by Sampson Handley, with the reservation that embolism may account for a certain number of metastases. The book is well produced and well illustrated; it forms an excellent addition to the literature on diseases of the breast.

Statique et résistance des matériaux. Par Prof. Paul Montel. Pp. vi+274. (Paris: Gauthier-Villars et Cie, 1924.) 30 francs.

THIS book is practically a reproduction of the lectures delivered at the École des Beaux Arts by Prof. Montel on statics and the resistance of materials. The range does not differ essentially from that covered by English text-books, but to those who have a penchant for geometric in preference to analytical proofs the book is to be recommended. Wherever possible geometrical demonstrations are adopted and numerical calculations effected graphically. A number of useful practical examples are to be found at the end of each chapter.

Letters to the Editor.

The Anomalous Emission of α-Particles from Polonium.

IN a recent issue of the *Zeitschrift für Physik*, Walther Kutzner has given the results of some careful measurements made with the view of testing the validity of Bateman's probability formula in its application to the emission of α-particles by polonium (*Vide Zeit. f. Phys.*, vol. 21, pp. 281–298, 1924). He arrives at the following conclusions :

(1) The emission of α-particles by polonium does *not always* obey Bateman's probability formula for a process of a purely fortuitous nature.

(2) Systematic deviations have been found to indicate a *subnormal* dispersion, *i.e.* the time intervals in which definite numbers of particles are observed occur more frequently, when the numbers lie near the mean value, than would be expected by the laws of probability. On the other hand, the time intervals corresponding to a large or to a small number of particles occur less frequently than theory predicts. (In other words, the familiar "cocked-hat" probability curve is higher at the crown and lower at the brim than would be expected from the theory.)

(3) It is found that the deviations are more appreciable, the greater the activity per mm.^{2} of the radioactive source.

(4) By allowing the source to decay, an improvement is found in the agreement between theory and experiment.

(5) The cause of this behaviour with polonium is discussed, and it is shown that, although the phenomena of scattering, surface oxidation, and diffusion of the polonium into the activated discs can influence the magnitude of the "subnormal dispersion," they are in themselves insufficient to explain the phenomenon mentioned in (4).

(6) For the explanation of this result it is suggested either that the individual radioactive polonium atoms mutually influence each other, or that the individual α-particles influence other atoms (atomic disruption).

From simple considerations one would not expect that an α-particle could approach the nucleus of a heavy atom sufficiently closely to bring about artificial disintegration, and hence it becomes imperative to examine whether Kutzner's results can be explained in a less drastic manner than that suggested under (6) above. The object of the present note is to show that effects identical with those observed by Kutzner are to be expected on the basis of the phenomenon of aggregate recoil, as usually obtained from sources of α-rays deposited on metallic discs. The importance of this phenomenon in the case of polonium was fully discussed in a paper by the present writer in 1919 (*Mitt. Ra. Inst.* Nr. 118, *Wien. Ber.*, vol. 128, pp. 795–830 ; also NATURE, vol. 102, p. 464, 1919), and has been confirmed by additional unpublished results, of which use will be made in what follows.

Electrolytic polonium does not consist solely of individual atoms on the metal disc, but an appreciable part of the deposit may exist in the form of aggregates of polonium atoms. Such aggregates are also formed in the case of the active deposit obtained by exposing a metal plate in emanation. When an α-particle is emitted in the direction of the plate from such an aggregate, the latter recoils from the plate, and in a vacuum leaves it entirely. Under such conditions one instance was noted in which the apparent decay of polonium was such as would correspond to a half period of 59·6 days, as compared with the true half period of 136·5 days. But even at ordinary pressures the rate of decay sometimes appeared to be so low as 127·1 days, so that even under normal conditions some of the recoiled aggregates may disappear from the plate. The number of aggregates per unit area and their complexity increase with the surface density of the electrolytic deposit, and, particularly under reduced pressures, it is the more complex groups that leave the plate first, in consequence of their containing more polonium atoms. In the course of time it follows that the polonium remaining on the disc is less and less complex, and indeed, after a sufficiently long time, one would expect the polonium remaining to consist almost entirely of individual atoms. As a matter of fact, aggregate recoil phenomena do become less marked with the lapse of time, owing to the degeneration of the aggregates, and many curious effects observed with radioactive deposits admit of simple interpretation on these lines (*e.g.* observations by Ratner, *Phil. Mag.* (6), vol. 36, p. 397, 1918).

Owing to the intense ionisation near the surface of a disc coated with polonium, it is easily seen that the aggregates, after recoil, may readily acquire a charge, and in circumstances negatively charged aggregates may preponderate.

Consideration of the above results supplies us with a ready interpretation of Kutzner's observations, for he used an electric counter of the Geiger type, in which a platinum point is enclosed in an outer metal cylinder or hemisphere, charged to a positive potential of more than 1000 volts, there being a small central opening in the front of the counter, covered with thin aluminium foil, through which the α-particles are admitted. In general, the distance of the radioactive source from the counter diaphragm, with respect to which it was centrally arranged, was from 5 to 7 mm., so that the intervening space would be subject to a strong electric field. From what has been said above, it is clear that many of the recoiled aggregates would be attracted to the aluminium foil closing the counter, so that the counts corresponding to the maximum of the probability curve would lie too high, whereas the limiting ordinates observed would be deficient. This is precisely what Kutzner noted (see (2) above). Moreover, since the formation of aggregates is enhanced for higher surface densities of the radioactive deposit, the deviations will be more marked in such cases (cf. (3) above). On the other hand, by allowing the polonium to decay, a progressive degeneration of the aggregates takes place, and the deposit acts more and more nearly like one composed of individual atoms, so that the agreement between experiment and theory improves steadily (cf. (4) above).

Using preparations of polonium of high surface density, Kutzner found, for a given source, that the deviations from theory were more considerable, the larger the aluminium-covered diaphragm through which the α-particles entered the counter. The number of transferred aggregates that are effective will obviously depend on the size of the diaphragm, being greater for larger diaphragms, so that such a result is to be expected, whereas it would be much smaller, or almost absent, when the same experiments were performed with a preparation of low surface density, and this Kutzner found to be the case.

By performing counts in which the source was first centrally opposite the entrance to the counter, and secondly, laterally displaced through 5 mm. with respect to the axis of the counter, Kutzner detected

a better agreement with theory in the latter case. This he ascribes to an influence of the direction of the α-particle beam within the counter, but it seems more likely that it was due to the fact that, in the second case, a smaller proportion of the transferred aggregates fell on the counter window. In another experiment, Kutzner found that with an unscreened source the deviations from theory were less than when the source was screened by a thin aluminium foil. This result may be, as he suggests, connected with the effects of scattering, but if the experiment were performed in the reverse order, one would expect that the screened source would give better agreement with theory than the unscreened.

Finally, Kutzner finds that counts with a willemite screen always yield results about 5 per cent. less than with an electric counter (*loc. cit.*, also *Zeit. f. Phys.*, vol. 23, p. 126, 1924). In view of the above, it is doubtful whether the whole of this difference is due to the inefficiency of willemite screens as compared with electrical counters, though it is generally recognised that deficient counts result from the scintillation method. It seems very probable that thin sections of willemite, as used by Kutzner, are more efficient than scintillation screens made from powdered willemite or zinc sulphide crystals. Were Bateman's formula to be tested by means of such screens, one would expect better agreement between experiment and theory than Kutzner found by means of the electrical counter, owing to the absence of an impressed electric field in the former case.

The deviations from theory in experiments by Rutherford and Geiger and by Hess and Lawson, to which Kutzner refers in his paper, are less systematic than his own. The former (with polonium) probably admit of the above explanation, whereas the latter were done with γ-rays and only for purposes of orientation.

ROBERT W. LAWSON.

Sheffield.

The Rotatory Dispersion of Tartaric Acid.

LONGCHAMBON (*C.R. Acad. Sc.*, vol. 178, p. 951, 1924) has recently found that the rotatory dispersion along the optic axes of crystalline tartaric acid is approximately the same as that of the lævo-rotatory component which contributes to the anomalous rotatory dispersion shown by solutions of the acid. The rotatory dispersion here referred to is measured by the ratio between the rotations for the blue (436 μμ) and yellow (578 μμ) lines of mercury. For the crystals it is 2·14, while for the lævo-component in solution it is estimated to lie between 2 and 2·22. From previous researches Longchambon had concluded that the rotatory dispersion of a given substance is a property which is conserved when the substance passes from the solid to the liquid state by fusion or solution. Applying now this generalisation to the case of tartaric acid, he states: "Le constituant gauche ne serait donc ni un anhydride ni un éther interne; ce serait l'acide tartrique ordinaire, *tel qu'il se trouve dans le cristal*; je l'appelerai 'acide tartrique α.' J'appelerai le corps droit 'acide tartrique β'; c'est la formation de cet acide β de l'acide α, par dilution ou élévation de température, qui produit les anomalies de dispersion rotatoire."

It seems appropriate now to compare these conclusions with those arrived at from the X-ray examination of the crystal structure of tartaric acid (Proc. Roy. Soc. A, vol. 102, p. 506, 1923). Out of this work it was suggested that the dextro-rotatory property of ordinary tartaric acid is associated with the carbon nucleus of the molecule, an arrangement of four carbon atoms which appears to exist in the crystal as an irregular tetrahedron, while the lævo-rotatory power is associated with the rest of the molecule manifesting itself principally through a twisted arrangement of the four hydroxyl groups, similar, but longer than and in an opposite sense, to the twisted arrangement of carbon atoms. "There is only one part of the molecule to which we can ascribe any degree of stability, and that is the nucleus of four carbon atoms arranged in an irregular spiral. Such effects as ionisation and hydration would tend to destroy the lævo-rotatory action of the four hydroxyl groups, *and it is probable that it requires the application of the forces which bind the molecules into the crystalline structure to complete the lævo-rotatory system.* Any change, such as fusion, solution, and certain chemical reactions, which leads to departure from the orientations which hold in the crystalline structure will tend to eliminate the hydroxyl spirals" (p. 527).

It thus appears that the work of Longchambon supports the conclusion arrived at from the X-ray analysis, that the lævo-rotatory component in solution is substantially the same system as that which produces the strong lævo-rotation in the crystalline form; that the tendency to crystallise and the act of crystallisation, though not unique as changes involving forces which enhance the lævo-rotatory power, are yet well-marked examples of such changes and lead finally, in the crystalline form, to the perfection and stabilisation of a lævo-rotatory system which completely overpowers the effect of the dextro-rotatory part of the molecule. From such a hypothesis it follows that, even in infinitely dilute solutions, since the molecule can never be stripped bare to the carbon nucleus above, the rotatory dispersion will still be anomalous. That this is experimentally true has been pointed out by Lowry and Austin (*C.R. Acad. Sc.*, vol. 178, p. 1902, 1924) in reply to the note of Longchambon. It also follows that the dispersion in the crystal, though the lævo-rotation overwhelmingly predominates, is probably not truly normal either. It is true that Longchambon says "la dispersion rotatoire est d'allure normale, mais très forte, . . ." but I presume this remark refers only to the region of the spectrum examined.

Early Canadian Experiments on the Acoustic Method of Depth Sounding for Navigation Purposes.

REFERRING to the article "The Acoustic Method of Depth Sounding for Navigation Purposes" published in NATURE of March 29, 1924, p. 463, it may be of interest to record some experiments carried out by the writer in 1915 on obtaining depths at sea by the echo method.

Having had much experience in carrying on fog alarm researches at Father Point, Que., for several years from 1913, the writer felt in the early days of the War that this site would be an admirable one for carrying out researches on submarine acoustics, with the view of solving some of the problems relating to the submarine situation in Europe. In addition to the facilities for experimental work, such as isolation, wharfage facilities, calm weather, easy access to a main railway line, etc., an important consideration was the fact that supplies of scientific material from America and co-operation with American men of science could be obtained on Canadian territory before the United States had yet entered the War.

In the early autumn of 1915 a plan and report to this effect was sent to the Minister of Marine and

Fisheries; and, while the question was being considered by the Canadian Government, a start at actual research was made with the co-operation of the Submarine Signal Company of Boston, Mass., U.S.A. It was decided to repeat the experiments of Prof. R. A. Fessenden (Trans. Am. Inst. of Elect. Eng., vol. 33, Oct. 1914, pp. 1569-1581) "On Obtaining the Depth of the Sea by the Echo Method." A Fessenden oscillator with the associated motor generator set was installed on the Canadian hydrographic survey ship *Cartier*, and during the month of October 1915, numerous experiments were tried on "depth sounding" (Fig. 1). A short experience showed that for moderate depths, 30 to 40 fathoms, the same oscillator could not be used for receiving the echo, on account of the persistence of transients in the electromagnetic circuits. A separate hydrophone, shielded from the oscillator signal by being placed on the opposite side of the ship, was therefore employed, and experiments, though for the most part unsuccessful on account of the weak echoes received from a sea bottom of soft ooze and clay, gave indications at favourable localities as to the ultimate possibilities of this method.

At this early date and under war conditions, it was practically impossible to obtain thermionic amplifiers

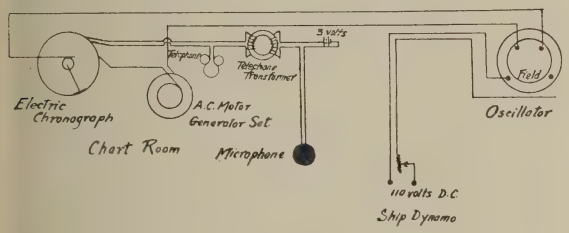

FIG. 1.

by means of which echo signals could be received. Then, too, for the faint echoes involved, the type of hydrophone available was not sufficiently sensitive, while for experimental work the type of oscillator available, weighing 1300 lb., was inconvenient for overboard use, especially with the ship in motion.

In a report submitted to the Electrical and Submarine Committee of the Admiralty Inventions Board, it was finally concluded that special transmitters of less weight, designed for inboard use, would have to be developed in conjunction with a more sensitive type of hydrophone. In order to obviate the use of thermionic amplifiers as much as possible, it was decided to make use of a hydrophone, suitably damped, capable of tuning in to the definite wave-length emitted.

A tuneable diaphragm, forming an essential feature of a hydrophone, was briefly described in the Proc. Roy. Soc., London (99-A, 1912, pp. 163-171). At the request of the Inventions Board the complete mathematical theory of electrically operated sound generator was undertaken, with the view of facilitating design.

It will be readily seen that a diaphragm both for emitting and receiving corresponds to the aerial in radio-telegraphy. In the latter field, the enormous advantage of the aerial tuning condenser for the selection of narrow wave-length bands is the characteristic feature of modern radio transmission and reception, an enormous increase in the range of communication having thus been effected. In just the same way, the writer anticipates a radical improvement in the art of submarine signalling by the introduction of tuneable diaphragms enabling specified wave-lengths to be picked up to the exclusion of others.

During the past few years the writer has been working at improvements in the construction of transmitters and receivers based on the principle of selective tuning, which it is hoped may find a useful field of application in an improved system of depth sounding for navigation purposes.

Study of Explosions.

SIR OLIVER LODGE, in NATURE of July 5, p. 10, suggests that the methods of producing the "Big Bangs," which have previously been used, may not be the most effective for the purpose.

While on service in France with the Artillery, it appeared evident to me that the noises with the greatest "carrying power" were made by the gun discharges, and not by detonations of high explosive shells.

The battery with which I was at the time was a 6-in. howitzer battery, and I noticed that the detonations of our own shells, although visually observed from an O.P. at 2000 or 3000 yards range, were often inaudible; whereas an enemy gun or howitzer at the same order of distance was always distinctly heard.

The noise of the great bombardment near Ypres in 1917, which was clearly heard from the South Downs in England, always seemed to me to be that due to the guns themselves, and quite unlike the characteristic "c-r-r-rumps" of H.E. shell detonations.

It seems possible that the detonation of a high explosive must produce an air wave of a very steep wave front, which may be damped out by the internal friction of the air particles more rapidly than the slower rise and fall of pressure produced by the combustion of the propellent type of explosive.

It is to be hoped that Sir Oliver Lodge's suggestion that in a future trial a charge of gunpowder or cordite should be exploded, in some form of container if necessary, at a considerable height from the ground, will be adopted.

P. J. RYLE.

Hadley House, Pangbourne,
Berkshire.

IN view of the recent attempts to utilize surplus munitions of war in the investigation of the propagation of sound in the atmosphere, it may be worth while to direct attention once more to the opportunity that explosions afford for investigating the propagation of seismic waves in the upper layers of the earth's crust. In the Oppau explosion 4000 tons of explosive produced a wave that was recorded by a seismograph at a distance of 365 km. This was a surface explosion. The momenta communicated to the air and the earth by the shock must have been equal, and therefore the amounts of energy that went into the air and the earth must have been in the ratio of the velocities; thus much less than a thousandth of the energy can have gone into the seismic wave. If, however, the explosive is buried deep in the ground, nearly all the energy will go into the earth. Thus a wave of intensity greater than that produced by the Oppau explosion could be produced by firing 4 tons of explosive underground. Further, timing could be made specially easy by having the explosion in wireless communication with the observatories, thus eliminating the uncertainty of the time at the focus.

St. John's College, Cambridge.

Different Types of Ions in Hydrogen.

In a previous letter (NATURE, June 16, 1923, p. 810), and more recently in the Proceedings of the Royal Society (105, p. 116, 1924), I described some experiments on the products of ionisation in hydrogen, nitrogen, and oxygen. It may be recalled that the method depended on the combination of an ordinary ionising potential arrangement with a simple positive ray analysis apparatus.

For hydrogen the principal conclusion drawn was that ionisation at 16·5 volts was not accompanied by dissociation. This conclusion rested on results at very low pressures where no atomic ions were detected below twenty volts and comparatively few even up to the highest voltages used. It was found, however, that at higher pressures the relative intensity of the atomic ions, H^+, became much greater, apparently due to a secondary dissociation of the molecular ions, H_2^+. No appreciable number of triatomic ions, H_3^+, had been observed at low pressures, and no search was made for them in the few experiments made at high pressures.

I have now set up an entirely new apparatus very nearly identical with that used in Cambridge and wish to report further results. The conclusion that the primary product of ionisation in the neighbourhood of 17 volts is H_2^+ has been confirmed. However, as the pressure is increased, it is found that H^+ does not necessarily become dominant. The effect due to H_2^+ becomes smaller and both H^+ and H_3^+ increase in intensity, but their relative size depends on the arrangement of the electrical fields (to be specific, on the strength of the field designated V_2 in previous communications). Thus, by varying conditions of pressure and electric field it is possible to produce almost any desired proportions of the three types of positive hydrogen ion.

The new evidence on a possible critical potential at about 20·8 volts corresponding to ionisation accompanied by dissociation is not conclusive, but makes its reality very doubtful.

The most interesting new result I have to report is, perhaps, the observation of peaks corresponding to apparent values of $m/e = 1/2$ and $1/3$. These are not attributed to anything so unexpected as doubly and trebly charged hydrogen nuclei, but merely to ions which have fallen through the entire electric field as H_2^+ or H_3^+, but which break up in the field-free space between the two slits before passing into the magnetic field. It is nevertheless remarkable that the atomic ions so formed should retain the direction and velocity of the original ions sufficiently to pass on through the magnetic field and produce a "peak." Obviously these results suggest a reinterpretation of the effects in nitrogen and oxygen previously attributed to doubly charged atoms. They also offer interesting possibilities for studying the mechanism of ionisation.

These points and others will be taken up in a full report of the work which I hope to write in a few months. H. D. SMYTH.

Transplantation of Heads of Insects.

It may be of some interest to biologists if I supplement Dr. W. T. Calman's letter under the title of "Chimæras Dire" (NATURE, July 5, p. 11) by a brief record of some experiments of my own. Not having any water-beetles available at the time, I tried to repeat Dr. Finkler's experiments on meal-worms. I cut off the heads of two pairs of specimens, and interchanged those of each pair. In a third case I had a single specimen which had recently moulted, and after removing its head put in its place that of another individual. The heads became attached to the alien bodies. I kept the specimens in Petri jars with a little meal. They made no spontaneous movements, but showed signs of life for a varying number of days, the maximum number being five. The signs of life in question were response to stimulation of the body with a blunt point. The head seemed to be dead long before the body. The only remarkable thing in the result of these experiments was the tenacity of life of the insect body after decapitation, and it may be doubted, especially after the results of Drs. Blunck and Speyer, whether anything more occurred in Dr. Finkler's experiments. J. T. CUNNINGHAM.

21 Gower Street, W.C.1.

Velella at Port Erin.

We have just found enormous numbers of the remarkable Siphonophore *Velella spirans* cast up by the tide in a neighbouring bay (Perwick). My daughter and a friend first noticed some specimens floating in a shore pool, and then we found abundance amongst the wet sea-weed at high tide mark, and picked up several hundreds in a few minutes. They were all dead, but many still showed the polypes and tentacles and the beautiful violet coloration.

This is not actually a new record for the Irish Sea, though a very rare event. A similar case was recorded, I think, in the first volume of the L.M.B.C. "Fauna of Liverpool Bay" many years ago, and probably indicates an exceptionally marked inflow of Atlantic water. Those who are now studying the variations in the movements of the currents and the plankton in British Seas may be interested to hear of this unusual occurrence. W. A. HERDMAN.

Port Erin, July 13.

A Rare British Oligochaet.

In Mr. Beddard's Monograph of the Oligochæta, p. 216, reference is made to *Rhynchelmis limosella* Hoffm., in these words: "There is every probability that it is a native of this country." I reported the finding of a specimen some years ago at Ringwood, but there was an element of doubt. Now, however, I am in receipt of an excellent specimen sent me by Mr. W. J. Lucas, which puts the matter beyond all question. Mr. Beddard thinks there is a specimen in the Oxford Museum, but I have had no confirmation of this. HILDERIC FRIEND.

"Cathay," Solihull.

Physical Properties of Clay.

The late Dr. R. Mullineux Walmsley was interesting himself in my work on the above subject, and for this purpose I lent to him my own special set of my five papers on the subject which were read before the Society of Engineers in the five years 1919–1923 inclusive. Unfortunately, this set has not been found among Dr. Walmsley's papers either at the University of London, the Northampton Polytechnic, or at his private house, and, knowing how careful he was, this points to his having probably lent the papers to somebody in connexion with the matter with which he was dealing. As the sets of these five papers are now so scarce, and especially as the set in question was my own private set, if this letter meet the eye of the person to whom the set was lent, I shall be greatly obliged if he will be so good as to return it to me. A. S. E. ACKERMANN.

Colours, Stains, and Dyes.[1]

By Prof. J. F. THORPE, F.R.S.

THE great majority of chemical substances occurring either as natural products or as the outcome of synthetic preparations in the laboratory are colourless. In other words, white light reflected from their surfaces or transmitted through these solutions is unaffected so far as its balanced colours are concerned and emerges unaltered. The absorption of light in these cases is general; that is, it takes place equally throughout the visible range of the spectrum and the object, therefore appears colourless.

On the other hand, there are a number of substances which possess the property of absorbing certain portions of the visible spectrum while reflecting or transmitting the remainder. These substances, therefore, appear to the eye to be coloured in accordance with the portion of the spectrum transmitted or reflected. A red substance is one which absorbs the blue region of the spectrum; a blue substance one which absorbs the red region, and so forth. This is known as selective absorption. Again, there are a number of substances, chiefly members of the carbon family, which have the power of absorbing rays outside the visible region of the spectrum—for example, in the infra-red or the ultra-violet—and these substances, since they possess selective absorption, must be regarded as coloured in a chemical sense, although the "colour" they transmit or absorb is not visible to the eye.

The hydrocarbon benzene is an example of the type of chemically coloured substance, and, as we shall find later, this property possessed by benzene causes it to be the parent substance of those very numerous and industrially important materials—the coal-tar dyes.

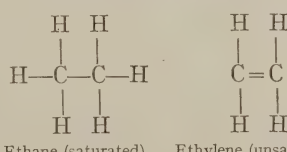
It is not in its lack of power to detect the ultra-violet range alone that the eye fails as an organ of vision, because even in the visible region its power to detect the end colours is seriously restricted. It is most sensitive towards green and red.

The power of a chemical substance to produce selective absorption is without doubt due to its chemical structure; that is to say, white light is "filtered" through the molecular structure of the substance, leaving a "portion" behind in its passage. The colour is therefore dependent on the chemical composition of the particular compound. On the other hand, it is possible to produce visible colour by entirely physical or mechanical means, as, for example, by ruling a number of fine lines on glass, and in these cases colour is independent of chemical structure, being entirely physical in character.

Nature, in producing the variety of coloured substances around us, has adopted both the physical and chemical methods to achieve her ends. The colour of flowers and leaves has been brought about by the use of coloured chemical substances, and these I shall deal with later. But many of the colour effects produced in the wings and feathers of birds and in butterflies are not due to the presence of any coloured substance in them, but to the arrangement of fine filaments or hairs, which serve the purpose of disintegrating white light and reflecting the desired shade of colour. The best test for this kind of colour effect is to examine the coloured object by transmitted light. If no colour is transmitted the reflected colour is probably due to physical causes.

A considerable number of the chemical substances which owe their colour to structure are inorganic in origin, and the colours depend mainly on the presence of some colour-producing metal; for example, chromium, cobalt, copper, and so forth. They are mostly used as pigments for the production of coloured surfaces by painting, or for the production of coloured decorations on china. Of these I do not propose to make any mention, not because they are unimportant as coloured substances, but because they do not trace any relationship to the stains and dyes which belong to organic chemistry, and are bound up with the recurrence of one particular element, namely, carbon.

There are some 300,000 definite compounds of carbon known, and the activities of research chemists add, perhaps, 4000 to these yearly. The majority of these compounds are colourless in the sense that they give only general absorption throughout the visible region of the spectrum. Some are, however, coloured—that is, they give selective absorption within the visible region—and it is evident that in these cases the colour cannot be ascribed to the presence of some particular metal, as with the metallic pigments, but must be due to some special condition of the element carbon. As a matter of fact, it is due to what is known as the "unsaturated state." The greater number of known compounds of carbon are "saturated" in the sense that all affinity which the carbon atom possesses for the atoms of other elements is fully satisfied. This is the case when carbon combines with hydrogen to form methane CH_4, or when it combines with oxygen to form carbon dioxide CO_2. No carbon compound of this type possesses colour, and every "saturated" compound shows general absorption of light. It is possible, however, to cause carbon to combine with carbon by more than one valency, and in such a case a condition of "unsaturation" arises:



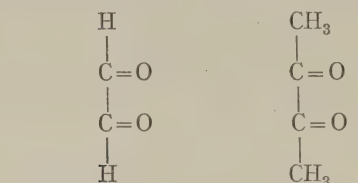
Ethane (saturated). Ethylene (unsaturated).

The affinity of each carbon atom is no longer satisfied by its proper quantity of hydrogen (or oxygen), and since there is naturally always a tendency for the substance to acquire the hydrogen atoms necessary for saturation, the "unsaturated" condition is definitely less stable than the saturated state.

The presence of one unsaturated linkage does not, however, confer colour on an organic compound—at least two being necessary for the purpose. It is also necessary that the two double linkages should be separated by one single linkage. This is known as the conjugated system of double linkages, and its presence in an organic compound apparently confers on it the property of producing selected absorption in the visible

[1] Discourse delivered at the Royal Institution on Friday, April 11.

region of the spectrum. The simplest possible coloured organic substances are therefore glyoxal and diacetyl:



Glyoxal. Diacetyl.

These substances, however, although they are of great interest as showing the origin of colour in organic substances, are relatively unimportant owing to their slight colour and their rarity. It is to the derivatives of the hydrocarbon benzene, upon which is based the chemistry of the coal-tar colour, that special interest attaches.

As already mentioned, benzene shows selective absorption in the ultra-violet region of the spectrum, and is therefore visibly colourless, although, chemically speaking, it possesses marked colour. The great number of the derivatives of benzene are, therefore, visibly colourless, but the chief point which has to be remembered is that, although visibly without colour, these derivatives possess potentially visible colour, and it is always possible to produce visibly coloured substances from them by modifying the molecular conditions which lead to the selective absorption causing visible colour.

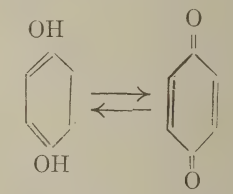
The organic chemist's conception of the structure of benzene is still that which was propounded by Kekulé some seventy years ago, and it is fair to say that no theory, either physical or chemical, has been brought forward since then which can be regarded as quite adequate. Kekulé regarded benzene as a substance containing a conjugated system of double linkages, upon which the colour of organic substances depends; but in order to account for the peculiar properties of benzene, its remarkable stability, and the formation of its derivatives, it is necessary to postulate a symmetrical formula which is expressed either by the Armstrong formula or by the simple hexagon—a necessity, which was met by Kekulé by the supposition that there was rapid dynamic interchange between the two unsaturated individuals of his formula. Below are given the forms of linkages which have been given to the benzene molecule, the carbon atoms, assumed to occur at the points of the hexagon, being omitted:

Kekulé (I). Kekulé (II). Armstrong. Conventional form.

This dynamic interchange, leading to symmetry, is expressed both by the Armstrong formula and by the conventional formula, but it is evident that each of them is merely a compromise, and represents an intermediate condition between two rapidly interchanging forms. They do not mean more than this, because any condition which postulates the existence of trivalent carbon has to contend with a number of cases in which the occurrence of this condition leads to instability quite out of keeping with the remarkable stability of benzene and its analogues and derivatives. This is the case with triphenylmethyl and similar compounds.

The dynamic conception of the structure of benzene supplies a reason for the recurrence of the strong ultra-violet absorption which is characteristic of this substance. Moreover, it suggests that if it were possible to modify the conditions leading to this absorption it might be possible to throw the absorption within the visible range of the spectrum, and thus produce visible colour.

The simplest visibly coloured member of the series is quinone, which is produced easily from hydroquinone by oxidation and is reconverted into hydroquinone on reduction:



Hydroquinone. Quinone.

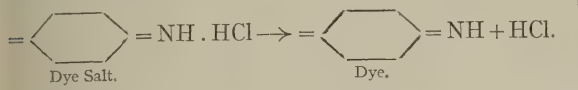
Here, then, at any rate, we have one means by which we can produce visible colour from a benzene derivative. There are certainly other means, but these are not as yet so clearly defined, and there is no question that when H. E. Armstrong propounded his quinone theory of colour he enunciated the fundamental principle on which the chemistry of the coal-tar colours is based. For there can be no doubt that the colours of these compounds are due to the presence in them of a quinone residue, which, acting like the simplest quinone ring shown above, throws the ultra-violet absorption of the visibly colourless benzene derivative into the visible region of the spectrum.

This is easily shown by the conversion of the visibly colourless phenolphthalein into its coloured alkali salt. However, it is a simple matter by altering the groups present to throw the absorption into any portion of the visible spectrum required, and thus to obtain any desired colour. The chemist is able, therefore, while retaining the same skeleton, to produce any colour at will by merely altering the nature of attached groups.

The name coal-tar colour is derived, of course, from the fact that the parent hydrocarbons from which the colours are derived—the benzene hydrocarbons and their analogues—are obtained by the distillation of coal-tar. The first of the series, mauveine, was discovered by the late Sir William Perkin in 1856, in an attempt to prepare the alkaloid quinine synthetically. But Perkin did more than discover a new series of colouring matters. He also introduced a new method of dyeing. Up to that time, dyeing had been a composite process involving the actual formation of the coloured substance on the fibre itself. The two chief processes in use were (*a*) that of vat-dyeing and (*b*) that of mordant dyeing. The first, represented by indigo dyeing, involved the reduction of the coloured substance (indigo) to indigo-white, a material soluble in alkali; the steeping of the fibre in the solution and the reproduction of the insoluble dye by means of the

oxygen of the air. The second required the previous impregnation of the fibre with a metallic hydroxide and the subsequent formation of a coloured lake on the fibre by steeping the prepared material in a dyestuff (alizarine) capable of yielding such a lake.

In each case, therefore, two distinct processes were involved. In the process introduced by Perkin only one operation was necessary. The dye contains, as already mentioned, a quinone or quinonimine residue, which causes the dyestuff in the form of its salt to be soluble in water:



It happens that the coloured base is soluble in the wool fibre, and when the fibre is added to the dye-bath the coloured base is extracted, leaving the mineral acid free in solution. The operation is of the same order as that which determines the extraction by, say, ether of an organic substance soluble in water. The coloured base is not, however, soluble in cotton, and hence this material is not coloured in the dye-bath.

These are known as the basic dyes; and a similar effect is produced by the acid dyes, although, since these are the sodium salts of sulphonic acids, the dye-bath has to be rendered acid previously in order to liberate the free sulphonic acids, which then dissolve in the substance of the wool. Cotton would not, of course, be coloured by this process, although, as it was found that the new basic colours possessed the power of giving an insoluble coloured compound with tannic acid and an antimony salt, it was possible to affix them to the cotton fibre by a two-process method, involving the previous treatment of the material with tannic acid and tartar emetic.

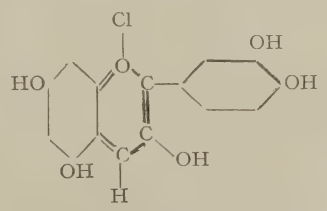
It was not until twenty years later that it was found (Böttinger, 1886) that a certain type of azo-dye derived from benzene possessed the property of being soluble in the cotton fibre, a discovery which led to the preparation of the large number of substantive cotton dyes known at the present day. In this case it is the sodium salt of the sulphonic acid which is extracted. This discovery was entirely accidental, but, as so often happens in organic chemistry, it was found that the property was possessed by a large number of substances of the same type, or having the same skeleton formation, and, since it is possible readily to alter the shade by varying the nature of attached groups, the series contains representatives of all shades of colour.

It must be remembered, however, that there is a marked difference between the two methods of dyeing —one, the older method, in which the dye is formed in the fibre, and the other, the newer method, in which the fibre acts merely as an extractor for the coloured base, acid, or salt. It is evident that, other things being equal, the older processes should give the faster dyeings; that is, the colour would be more firmly fixed in the fibre and less likely to be affected by the various conditions, such as exposure to light, washing, etc., to which a dyed fabric has usually to be subjected. This is, as a matter of fact, the case, and numerous processes have been devised by which the stained fabric (as I prefer to call it) can be rendered more fast by after-treatment; that is to say, by causing another colour to be produced in the fibre from the colouring matter already there. One of the best illustrations of this is the method by which an azo dye can be produced on the fibre from a stained fabric which has been stained by a substance having an NH_2 group:

$$-NH_2 . HCl \rightarrow -N=NCl \rightarrow -N=N . R . OH.$$

There are many other methods, such as after-treatment with metallic salts, or with formaldehyde, which can be employed. Indeed, such processes would be still more necessary were it not for the remarkable tenacity with which the stained fabric, in many cases, retains its stain. The affinity varies in different cases, both as regards the power and speed of absorption, and is probably connected with the size of the molecular (colloidal) aggregates which are present in the dye-solutions. It is not connected with the actual molecular weights.

Nevertheless, although there are some stains which possess so marked an affinity for the fibre as to render them comparable with true dyestuffs (those produced on the fibre) in fastness, and some which lend themselves to after-treatment, and fall therefore within the category of true dyestuffs, there are a large number which possess all the inherent disabilities of the class; that is, they are unsaturated organic compounds tending to pass into the saturated (colourless) state under favourable conditions. Such conditions are always present in the oxygen of the air, which in the presence of light constitutes a formidable opponent to all coloured organic compounds. As already mentioned, Nature got over this difficulty in the case of bird's feathers and butterfly's wings and also in the wing cases of coloured beetles by ignoring the organic colour altogether. She utilised them, however, in the case of the flowers, but chose substances highly oxygenated in structure, which would be least likely to be affected by air and light. For example, the colour of the red rose is delphinidine,



and this is also the basis of the colour of the blue cornflower, the only difference being in the character of the group attached to the oxonium oxygen.

However, as the science of organic chemistry advanced, it became possible to contemplate the synthetic preparation of some of the natural colouring matters, of which indigo, alizarine, and logwood were types. These are not natural colouring matters in the sense that they are used by Nature as such, but have been evolved by man for his own purpose by a process of trial and error. They represent the survivors of a vast number of natural substances with which man must have experimented throughout the ages in order to produce colour for his own purposes. Together with certain mordant colours derived from lichens, which are still used for dyeing in certain parts of the country, they constituted the sole means of producing

dyed fabrics at the time when the coal-tar colours were discovered. Their value as dyestuffs was without question, the world's yearly consumption of indigo alone, at that time, representing some 4,000,000*l.*

It must also be remembered that it was not the question alone of the commercial production of the dye in competition with the natural product which was sought, because this must have appeared a totally impracticable problem in those early days. It was rather the search for the reason why alizarine was a mordant dye and why indigo was a vat-dye which was the incentive to research, because when these facts were discovered other substances having similar properties could be prepared. The attack in every case followed the usual lines. In the first instance, the structure of alizarine (the mordant dyestuff of the madder root) was revealed by analysis, when Baeyer found that it gave anthracene on distillation with zinc. Its synthesis from the anthracene of coal-tar followed in the next year, being effected almost simultaneously by Graebe and Liebemann in Germany and by Perkin in England. In this case the preparation was so simple and the raw material so easily obtained that the natural madder industry was rapidly killed. The determination of the formula and synthesis of alizarine showed the particular grouping, namely,  , on which mordant dyeing depended. Hence the preparation of a large number of analogues of varying shades of colour followed.

The determination of the structure of indigo took longer, and occupied Baeyer at Munich some eighteen years. In this case the colour was synthesised and manufactured on a commercial scale three years before its structure was determined, because, as sometimes happens, a reaction, the course of which was then unknown, led to the formation of the dye. Here, again, the determination of structure showed that the property of vat-dyeing depended on the presence of the grouping  , and in consequence, whereas blue indigo was the only known member of its class in 1890, at the present day every shade of colour is represented in this particularly fast series.

Finally, at the beginning of the present century, the accidental discovery of indanthrene by Bohr placed on the market the first member of a series of vat-dyes, which constitutes without question the fastest series of colouring matters hitherto prepared. Practically all shades of colours are represented, the principle of dyeing being essentially the same as that of indigo.

Before the War we relied mainly on Germany for the production of our dyestuffs, and, what was still more serious, we left to them the research work on which the production of new dyestuffs depended. Dyestuff chemistry is merely a branch of organic chemistry, which includes also the preparation of organic chemical substances used in a variety of industries essential in peace and war. The possession of a dyestuff industry implies, therefore, the possession of a band of trained organic chemists and, what is more important, the possession of university and university college laboratories, where organic chemists can be adequately trained in methods of research. As a member of the Dyestuffs Development Committee, it has been my good fortune within the past six months to visit all the dye-producing factories operating in Great Britain, and I have been struck with the very real success which has attended the efforts of the past five years to establish the industry. If we had merely reached the level of excellence attained in Germany before the War, the fact would have been very creditable, but we have done more than this, and in several cases, notably in the production of a new indanthrene green, we have already drawn ahead; a position, it is to be hoped, we shall not again lose.

Some Geographical Aspects of the British Empire Exhibition.

THE British Empire Exhibition at Wembley, in the north-west outskirts of London, strikes at once a note on the Empire as a unit. From the Palace of Engineering, with its sense of the fullness of the metallurgical industries of Britain, across the way to the Palace of Industry, almost crowded out with the multifarious products of Britain's factories, one gathers an impression of diversity as shown by fountain-pens and gramophones in contrast with big guns and giant railway engines, of high quality from the silks and laces to the coach-work on the motor cars, of stability from the various types of safe and strong room to the giant turbines; and, withal, there is a feeling of much energy crowded into a tiny space. Visit may succeed visit to these two great palaces, the main monument to the occupations of Britons at home, and yet their innermost recesses, their by-ways, and their out-of-the-way corners would not all be explored; it would appear that the visitor is left deliberately with few indications of the wealth of British products here housed, for each visit brings to light something previously missed and leaves the thought that there is yet something more to find.

The British Isles are thus presented as a crowded hive of industry, and this impression is intensified when one penetrates below the surface. Mannequin parades, exhibits of machine processes in cotton, paper, and so forth, are co-operative efforts; they are not labelled as the work of one firm or as, necessarily, the product of one district; they are specimens of Britons' work. The student of geography who wishes to emphasise or correct his book-lore is driven to much mental effort to analyse the contents of these great buildings, to sort out the products, say, of the Black Country and to localise the various elements of industrial Britain. Except in a few instances, mainly in the food section, the visitor is not asked to buy, and the exhibit is not primarily designed as an advertisement; in this respect the student would penetrate deeper and more easily into the mysteries of British manufactures at one of the annual trade shows, such as the British Industries Fair or the Motor Show. Of course, customers from overseas can get into touch with manufacturers, but the trading element, the business of selling the goods, is kept in the background; here is primarily an exhibit of what

can be produced by the British Isles as the chief congeries of factories in the Empire.

Over against the impression of works jostling with works to pour out useful commodities for use throughout the Empire lies the first, and the dominant, feeling which is aroused by the pavilions devoted to Australia, Canada, and New Zealand. Each of these suggests life in the open spaces where there is room and to spare for all; a largeness and perspective about the exhibits strikes immediately the right note. In the same spirit the divisions of the country are obscured; it is intentional that the visitor should have to make an effort to discover whether he is examining the products of New South Wales or Victoria, of the Canterbury Plains or Taranaki. Take the simple matter of apples; the housewife at home is concerned with the quality of the fruit, not with the location of the orchards; in each pavilion she may see and buy fine specimens, and she carries away the notion that the greengrocer may supply Canadian, Australian, or New Zealand apples; she may see adjacent pictures of Canadian orchards and only after diligent inquiry learn that one picture shows life in the Annapolis Valley and the other a scene in British Columbia, places 3000 miles apart. Similarly, butter is seen in refrigerating chambers in Canada and New Zealand, sheep are sheared in Australia, timber of all kinds, undressed, dressed, worked into furniture, is shown from all three countries. Canada invites attention to her magnificent water supply with its uses for power installations; Australia indicates by a model farm the irrigation of an arid area.

In these pavilions, as elsewhere, the complete exhibit is a concrete demonstration of the products of each country as a whole, and the best guide to the pavilion is probably a list from a Blue-book of the products of each land; there is little attempt to indicate relative importance; each country says simply, This is what we can do, this is our contribution to the Empire's needs, will the Empire make use of our efforts?

In this regard the main part of each show deals with a few primary products, meat, wool, ores, timber, but a similar note is struck regarding the factory products of the chief towns. Emphasis is not laid upon the work of Toronto in competition with Montreal or of Melbourne rather than Sydney, but upon the one main fact that Canada and Australia can make house furniture, boots and shoes, apparel, and so on, of a quality which exceeds expectation. Canada is not merely a farmer's land, a land of the backwoods and prairie; Australia is more than a home for the squatter or the bushranger. Even the prairies or the Australian back-blocks are no longer the scene of primitive human labour, that of the hands; the prairie quarter section is depicted near a railway with a convenient elevator against which a moving train stops until the grain has poured into the truck; Australian sheep are sheared and Australian cows are milked by machinery.

Leaving the spacious lands the visitor reaches, in turn, India, Burma, and Ceylon, and again receives the right impression of crowds and ceaseless activity, but with this difference, that the activity is concerned, on the whole, with products each of small import. So there comes before him the questions of cotton, tea, and rice. In the Palace of Industry a cinema has told him the story of cotton, and machinery has whirred and clanged as the fabrics were made before his eyes; here are the raw material, the native weaver, and the native product all in readiness for the contrast to be obtained from a subsequent visit to the African pavilions to find experimental cotton growing and other native looms at work.

Here, and more forcibly at Hong-Kong, the spirit of the Eastern bazaar is displayed; here is the peddling of home-made products and the country's curios. Rightly, perhaps, the primitive elements of Indian life are hidden except in relation to the ameliorative work of the missions, India being presented rather from the point of view of the business and needs of the Empire than from that of a true perspective picture of what Indian life is like in all its degrees.

Thus the visitor passes to the smaller sections of the Empire, the best guide, as always, a Blue-book list of products, cocoa, kola, palm oil, rubber, and so on, for the Gold Coast, for example, and in addition, both within and without the pavilions, a skilled attempt to produce the essential atmosphere of the colony with native craftsmen, native scenes, and the products of domestic industries. The tour so far has been a continuous descent in the scale from the English locomotive and the Canadian motor-car to the Indian shawl and the West Coast brass or silver bowl with a hammered pattern, from a Doulton vase to a piece of African pottery. Diamonds, gold, ostrich feathers in South Africa, fish, paper-making, and the Newfoundland dog in Newfoundland, oranges in Palestine, an interesting historical exhibit in Malta, whaling and sealing in the Falklands, copra in Fiji, are but a tithe of the things to see in the remaining pavilions.

Imperial communications are focussed in an interesting model in the Government pavilion, but they are constantly to the fore elsewhere, either in the separate pavilions of the Canadian railways, or as specimens of railway carriages or ship's quarters or as model steamers or models of docks and wharves in the several Imperial units. The would-be settler has every inducement to find out all he wishes to know about any land which attracts him, and Imperial comparisons are possible under the guidance of the Department of Overseas Trade.

Health questions in the Empire are dealt with in the Government pavilion in a section which deserves to become more popular.

In every corner the visitor is carried away to some distant land, from every detail he gathers a suggestion which leads cumulatively to a notion of what each name, Malaya, British Guiana, East Africa, implies, and even a scamper of merely one day's visit through the several pavilions gives reality to these far-off homes of Britons overseas, and the wise visitor probably pauses and looks back over the pavilion itself to grasp the message it conveys; the colour scheme of West Africa, the caribou and bison of Canada, the Maori whare and Samoan hut, the pillars at the entrance with the pagodas of Burma, the Indian pavilion as a whole, all contribute to the general effect, which is intensified by the slow passage over Old London Bridge with the views from either end, the old heart of the Mother City brooding over the wonders brought into being by her sons, the Empire builders.

The Toronto Meeting of the British Association.

LOCAL ARRANGEMENTS.

(From our Toronto Correspondent.)

THE local arrangements for the Toronto meeting of the British Association in August give promise of an interesting time for visitors from the east side of the Atlantic. Committees have been busily engaged with arrangements for local entertainments, sectional excursions, and the main excursion through western Canada to the Pacific coast, which is to take place after the meeting. It is now possible to give a summary of the arrangements which have been made.

The main party of visitors from England is expected to arrive in Quebec on August 2. There they will be formally and appropriately welcomed, and will spend a day at Quebec, leaving late in the evening. They will arrive in Montreal on the following day, and accommodation is being reserved at hotels where visitors will spend a welcome day of rest. On August 4 excursions have been arranged to Macdonald College and to the Port of Montreal. A botanical excursion has also been arranged. While definite plans have not yet been made, it is proposed that the party be divided in Montreal into two approximately equal groups. One of the groups will leave for Ottawa late in the evening of August 4, and will spend the morning of August 5 there, take part in certain official functions and entertainment, and leave for Toronto at midday. The other group will go directly from Montreal to Toronto by night train on the evening of August 4, arriving in Toronto on the Tuesday morning.

For the social side of the meeting in Toronto, several garden parties, receptions, ladies' luncheons, and other entertainments have been arranged. Among these are a recital of Canadian music and the performance of a Canadian play in the theatre of Hart House. An exhibition of Canadian paintings will be on view throughout the meeting at the Toronto Art Gallery, which is five minutes' walk from the University.

On Thursday, August 14, a general excursion has been planned to Niagara Falls. Other excursions to Niagara Falls and its vicinity will be undertaken by sections for their own purposes, and it is suggested that those who wish to go to Niagara primarily to see the Falls should take part in this excursion on August 14 to avoid unnecessarily enlarging the sectional excursions during the meeting.

The following sectional excursions have been planned:

On August 8 the Chemistry Section will visit the industrial plants around Niagara Falls, Welland, and St. Catharines. On this excursion the chemists will spend the night at Niagara Falls.

The Geology Section will make the following excursions:

On the afternoon of August 7, together with a limited number from the Geography Section, they will travel by motor-cars to various points in the vicinity of Toronto where palæozoic rocks may be seen. The party will be under the direction of Prof. Parks, of the University of Toronto, and is limited to fifty. On the afternoon of August 8, under the direction of Prof. Coleman, they will visit various localities in the vicinity of Toronto for the purpose of studying glacial phenomena. This party, which will travel in motor-cars, is limited to seventy-five. On August 9-10 they will visit the Niagara-Grimsby district under the direction of Profs. Coleman and Parks. This excursion is limited to sixty participants. If a sufficient number desire, arrangements will be made for another excursion to the Pre-Cambrian area in eastern Ontario. This excursion would leave Toronto on the evening of August 8, and return on the evening of August 10. It would afford an opportunity for studying the Laurentian and Grenville formations.

In the Zoology Section there will be a motor trip on the afternoon of August 8 to the Forks of the Credit River; on the afternoon of Monday, August 11, a motor-launch trip on Lake Ontario for the purpose of examining the plankton; and on the afternoon of August 12 a motor-car excursion to Schomberg Swamp on the Holland River.

In the Engineering Section on August 9 the engineers will journey by steamers and cars to various engineering works, such as the Welland Canal and the Queenston Power Plant, in the vicinity of Niagara. This excursion will occupy the whole day. On August 11 they will inspect the works of Toronto harbour, making the tour by boat.

The Psychology Section will make a motor excursion to the Ontario Hospital at Whitby on August 9.

The botany excursion will visit High Park, Swansea, and Humber Valley on the afternoon of August 7. And from the evening of August 8 to the evening of August 10 they will camp in the vicinity of Niagara Falls and make various excursions to points of interest to botanists. On the afternoon of August 12, provided with footware suitable for wading, they will visit the Sphagnum Marsh on Holland River, 33 miles north of Toronto, returning to Toronto late in the evening.

The following sectional excursions will take place after the meeting:

A party of geologists, limited to twenty-four, will leave for northern Ontario on the evening of August 14 in a special Pullman car, and will spend the following five days at Temagami, Cobalt, Kirkland Lake, and the Porcupine district. Those geologists who are going on the western excursion will join it on August 19. The northern Ontario excursion will be free of any expense, and members taking part in this and the succeeding botanical excursion will be guests of the Provincial Government of Ontario until they join the western excursion.

A party of botanists, limited to twenty-five, will also leave on the evening of August 14 for Temagami, and will proceed to the summer station at Bear Island. This excursion, which will entail no expense to the participants, will join the western excursion at Temagami early on Monday morning.

Members of the Agricultural Section will visit fruit farms in the Niagara district on August 15. They will also visit certain stock farms and the Ontario Agricultural College at Guelph. They will spend the night of August 15 at Guelph and return to Toronto in the afternoon or evening of August 16, in time to join the western excursion.

The Western Excursion.—This excursion, as has already been announced, will journey from Toronto to

Vancouver and return. Two trains, half an hour apart, will leave Toronto on the evening of August 17. The trains will proceed westward by the Canadian National and Temiskaming and Northern Ontario Railways, and return by the main line of the Canadian Pacific Railway in time for those sailing from Montreal or Quebec to catch their steamers on September 4. An opportunity will be afforded to visit mines and concentrators at Cobalt, and the mines and mills at Kirkland Lake and Timmins. A day will be spent at Winnipeg, a half day at Saskatoon. At Saskatoon a meeting of the Chemistry Section will be held at the University of Saskatchewan, and a new chemical laboratory will be formally opened. Another day will be spent in Edmonton, where Sections C and K will hold short meetings at the University of Alberta. A short visit will be made to Jasper Park.

Arrived at Vancouver, members desiring to do so may visit Victoria by steamer. In Vancouver and its vicinity visits will be paid to great saw-mills, salmon canneries, and copper mines, and short technical sessions will be held at the University of British Columbia.

A train will leave Vancouver on August 26 and 27 respectively. The first train will make stops of suitable lengths at Glacier, Lake Louise, and Banff, and the second at Lake Louise and Banff. From Banff eastward the trains will travel half an hour apart, and stops will be made at Calgary, at Fort William, and at Port Arthur, where the grain elevators will be visited. The trains will also stop at Sudbury, where the mines and smelters of the famous Sudbury nickel region will be the last important feature to be studied.

As has been already announced, the expense for this excursion, including sleeping accommodation, will be 100 dollars return. Meals will be provided on dining-cars. The local committee is endeavouring to get especially low rates for meals, but it is unfortunately not yet possible to announce what these rates will be.

Appropriate guides with detailed itineraries have been prepared for the western and other excursions, and will be issued at the reception room during the meeting. It is unfortunate that the demand for space on the western excursion has been so great that it will be necessary to limit the number of those participating, who will be chosen from the list of applicants during the meeting. Needless to say, preference will be given to overseas visitors.

Obituary.

SIR SYDNEY RUSSELL-WELLS.

BY the death of Sir Sydney Russell-Wells, which happened with tragic suddenness on Monday, July 14, the cause of education, and especially of university education in London, has suffered a heavy loss. With no outstanding scientific achievements to his name, no published work that could be called noteworthy, the founder of no scientific school of thought, he nevertheless succeeded by dint of courage and perseverance in winning a place of honour as a friend of educational development and as a university administrator.

A Londoner by birth, Sir Sydney Russell-Wells received a sound training in science at the old Royal College of Science and University College, proceeding afterwards to St George's Hospital Medical School, where he had a distinguished career culminating in the passing of the London M.D. in 1895. He held the appointment of Senior Physician at the Seamen's Hospital, Greenwich, and of Physician at the National Heart Hospital. In more recent years, while retaining all his interest in general medicine, he tended towards specialisation in diseases of the heart, and won a reputation as a sound and trustworthy diagnostician.

But it was in the University of London that Sir Sydney Russell-Wells's main interest lay, in the University in which he had graduated in science and in medicine, and which at the time of his death he represented in Parliament and on the General Medical Council. Into the controversies of the University he threw himself in his earlier days with keen interest, with knowledge, and, it must be added, with zest. When, however, an opportunity presented itself of rendering service of a positive, constructive kind, he was not slow to avail himself of it. To him more than to any one is due the existence of the School of Commerce in the University, and to him the recognition, tardy but generous, on the part of the City of London of the fact that there was a great University in London. When in 1920 he was elected Vice-Chancellor of the University, he set himself deliberately to the task of impressing the University upon London, and there is no doubt as to his success. His methods were perhaps open to criticism at times, especially among some of the older members of the University, but no one doubted his zeal and energy, his passionate faith in the future of the University, and his jealousy for its rights and prerogatives.

Sir Sydney Russell-Wells's tenure of the office of Vice-Chancellor lasted nearly three years, and the occupancy of the post undoubtedly broadened his experience and enlarged his outlook. He had been a doughty exponent of the claims of the external student, and while he held consistently to the view that the University merely as an examining body was an agency for good, closer acquaintance with its teaching work, which during his Vice-Chancellorship had enormously expanded, filled him with enthusiasm, and he never ceased to play the part of reconciler between opposing schools of thought. He was also largely responsible for the difficult and intricate negotiations which led to the acceptance of the Bloomsbury site for the University. Much of his work was accomplished under great difficulties, for although he was a skilful and well-informed conversationalist and most persuasive talker, he had no gifts of oratory, and his health, never strong, was taxed severely by the strain he put upon himself. But he kept grimly on, knowing, as he must have known, that he would have to pay the price. He died at his work, and his devotion to it and to his University will be long remembered by his friends and his colleagues.

AT the moment of going to press, we learn with much regret of the death in London on Monday night, July 21, of Sir William A. Herdman, emeritus professor of natural history in the University of Liverpool and president in 1920 of the British Association.

Current Topics and Events.

A SOCIETY for Cultural Relations between the peoples of the British Commonwealth and the Union of Socialist Soviet Republics has been founded recently in London. The objects of the Society are: (1) To collect and diffuse information in both countries on developments in science, education, philosophy, art, literature, and social and economic life; (2) To organise lectures and an interchange of lecturers, conferences, exhibitions, etc., and to arrange for the publication and translation of papers and books; (3) To provide opportunities for social intercourse; (4) To take any action deemed desirable to forward the intellectual and technical progress of both peoples. Russia has unfortunately been cut off from all other civilised countries for about ten years, owing to the War and the revolution which followed it. Only in this year has it been possible to break down some of the wall separating Russia from other peoples. Through the crevices Europe begins to see that, in spite of the most difficult conditions prevailing in science and art, the great spirit of Russia is still alive and even active. Hunger, shortage of necessary technical materials, apparatus and books, the necessity of working in rooms and laboratories where the temperature in winter was near freezing-point, prosecution by the Government—all this has not killed the spirit of Russia. The attempts of the Government to proletarise science and art have not been very successful for a simple reason, namely, there is only one truth, the same for proletarians and bourgeois, the desire for which is that peculiar feature which distinguishes a man from an animal. For Russians the breaking down of the wall surrounding their country has become much more important than for countries which are outside this wall: the development of western science, art, literature, philosophy, and social life, which is free and not "controlled" by Government and has proceeded under normal conditions of life, has resulted in remarkable progress. There is no need to point out how vital the knowledge of this progress is to Russia. From this point of view, it is necessary only to wish all success to this new society, provided it does not become an official organisation, but remains free from any official control and concerns itself only with the promotion of friendly relations between the intellectual representatives of both countries.

BY the retirement, after fifty years of service, of Dr. H. J. H. Fenton, who went to Cambridge in 1874 as an undergraduate of Christ's College, the University has lost a well-known personality and the Chemical Department a distinguished man of science. Dr. Fenton has taken part in the development of chemistry in the University from its infancy, since he became junior demonstrator, under Prof. Liveing, some years before the new laboratories, the nucleus of the existing buildings, were completed and occupied in 1888. In 1886 Fenton published an investigation on the hydration of ammonium carbamate to ammonium carbonate in aqueous solution, in the course of which he employed a novel method of analysis depending upon the fact that sodium hypochlorite sets free only the ammonia nitrogen, whilst sodium hypobromite liberates the amide nitrogen as well. In 1894 he began a fruitful series of researches on the oxidation of hydroxy-acids by hydrogen peroxide in the presence of traces of ferrous iron as catalyst. At an early stage of this work he prepared from tartaric acid the interesting compound dihydroxymaleic acid, and by heating it with pyridine obtained the simplest sugar, glycollic aldehyde. In 1899 Fenton and Miss Gostling discovered the chloro- and bromo-methyl furfuraldehydes, which they obtained by treating ketohexoses or cellulose with the corresponding halogen hydrides. Apart from their intrinsic interest, these compounds formed the basis of new colour tests for certain classes of compounds; *e.g.* by treating bromomethylfurfuraldehyde with malonic ester in the presence of alcoholic potash a fluorescent material was produced, which Fenton showed could be employed to distinguish hexoses from pentoses. Another interesting substance, termed by Fenton methylfuril, gave colour-reactions with primary amines and carbamides. Readers of Fenton's "Outlines of Chemistry" and of his more elementary "Physical Chemistry for Schools" will obtain some idea of the scope of the material which formed the basis of his lectures, but only those who followed the lectures were aware of the masterly treatment of the subject. His "Notes on Qualitative Analysis" constitute the *vade mecum* for thousands of students of that particular branch of practical chemistry.

AN exhibition is now being held in the Assyrian Basement of the British Museum of some of the objects found by the Joint Expedition of the Museum and the University Museum of Philadelphia to Mesopotamia during 1923–24. The principal objects now shown were found around the Temple platform at Tell el-Obeid about five miles from Ur. Of these, the most important, from the historical point of view, is the marble foundation tablet bearing the hitherto unknown name of King A-an-ni-pad-da of the First Dynasty of Ur, which dates back to before 3000 B.C. The exhibit includes a pictorial representation by Mr. C. L. Woolley of the walls and entrance of the temple as they stood originally. This enables visitors to appreciate the significance of the remarkable collections of models of animals and the friezes in bas-relief which adorned the walls with representations of animals and scenes of agricultural life. A wonderful copper statue of a bull some 2 ft. 4 in. high and 2 ft. 8 in. long is undoubtedly the oldest hollow statue now known to exist. It reveals a remarkably high technique for so early a date. It was made by carving the body and limbs in wood separately, and fastening them together with copper wire. Thin copper sheets were then hammered over the whole. The exhibition includes several examples of the use of different coloured *tesseræ* inlaid in bitumen for decorative purposes. The collection will be on view for about two months before it is apportioned to the British Museum, Philadelphia and Baghdad.

THE Natural History Branch of the British Museum, which started its series of picture post-cards not long ago, has gone ahead with them rapidly. Some beautiful examples in colour have been produced by Messrs. Stone, Waterlow and Sons, and W. F. Sedgwick. Of these, 70 cards illustrate insects, 10 birds, 5 reptiles, and 15 plants; and 20 cards represent 122 eggs of British birds. The monochrome series comprises 20 views of the building, 90 mammals, 35 birds, 40 insects, 25 plants, 60 fossils, 15 meteorites, 15 reptiles, 10 corals and sponges, and 10 rare and curious natural history books. Among recent additions, those in colour of British flowering plants promise to be as useful as they are attractive; each shows a plant or spray in flower, a single flower, fruit, and sections; they are made from drawings, but the name of the artist is not given. There are three sets of very life-like reptiles and batrachians, presumably from exhibited specimens. Miss Alice B. Woodward, who worked under the guidance of the late C. W. Andrews, has contributed six characteristic reconstructions of extinct mammals, mainly Proboscidea. New ground is broken by a set illustrating the life history of the common eel, based on the memoir and photographs by Dr. Johs. Schmidt. The educational value of all these cards is considerable, and teaching establishments not already acquainted with them should write to the Director for the latest list.

THE statement of activities of the National Research Council of the United States for the year ending June 30, 1923, is now issued as Circular 49 of the Council. It appears that the Council now derives the whole of its finances from other than Government sources, and is in consequence entirely controlled by its own chosen officers. Its budget for the year was half a million dollars, and in addition it is spending one and a third million dollars on the new building at Washington to accommodate the Academy and the Council, described in NATURE of July 22, 1922, p. 120, and June 28, 1924, p. 940. It maintains about 100 post-doctorate research fellowships in physics, chemistry, biology and medicine from funds derived from the Rockefeller Foundation. Under its sponsorship a considerable number of special organisations carry on research on physical, engineering, chemical, geological, biological, anthropological, psychological and medical questions, such as the structure of the atom, research chemicals, petroleum, sex problems, immigration, food and nutrition. There can be no doubt as to the determination of the people of the United States to make their country a great centre for research, nor as to the energy with which they are carrying out their intention.

IN his presidential address to the Society of Chemical Industry, delivered on July 9 in Liverpool, Dr. E. F. Armstrong referred to the success of the chemical exhibits at the British Empire Exhibition, of the chemical literature which has been issued in connexion therewith, and of the Bureau of Chemical Abstracts, which has been formed to prevent overlapping in the abstracts that are issued by the Chemical Society and the Society of Chemical Industry. On the other hand, he deplored recent signs of increasing competition between the various chemical societies, and the inaction of the Federal Council for Pure and Applied Chemistry in regard to the further consolidation of chemical interests and the establishment of a central Chemistry House. The greater part of the address consisted of a dissertation on the fats, written in collaboration with Mr. John Allan, which gives an excellent survey of existing knowledge and problems in this important field, and would be still more valuable if it had been published with full references to the original literature.

A MARKED degree of success appears to have attended the tests of wireless reception and transmission to and from a moving train carried out by the Radio Society of Great Britain on July 4. An experimental apparatus both for sending and receiving was installed on the express train leaving King's Cross at 7·38 P.M. for Newcastle, and signals transmitted from the train were received at distances of more than 200 miles. Observers in London could hear the signals distinctly while the train was approaching Newcastle (268 miles from King's Cross), and reception was reported from localities so far distant from the line as Shrewsbury and Glasgow. In spite of the deafening noise of the train, and other difficulties, the receiving apparatus worked satisfactorily, and those on the train were in touch with the transmitting station of the Society at Shepherd's Bush, London, while the train was passing through Darlington at 65 miles per hour. An experimental station at Bedford was kept in touch with for more than 150 miles. The complete analysis of the results is not yet available, but enough has been done to show that wireless communication with moving trains is a practical proposition.

THE Southend-on-Sea Public Museum (Prittlewell Priory) has just been enriched by the gift by Major Weber of the Hoy collection of birds (1797–1839). With one or two exceptions the Hoy collection is complete and consists of more than 260 cases. Most of the birds were taken in Essex, Suffolk, and Norfolk, and the collection contains many rare and valuable specimens. Among these are the first recorded British specimen of the pectoral sandpiper, bustards, ospreys, and eagles. The Southend Museum contains also the Christopher Parsons collection of birds (1807–1882) from south-east Essex, and since the Museum was opened in 1922 many rare bird visitors to the county have been secured by purchase, these including the first specimen of the yellowshank recorded in the eastern counties and the third in Britain; the smew; blue-headed wagtail; and numerous other birds. Major Weber's gift, added to the existing collection, makes the ornithological department of the Museum noteworthy among collections of local birds in Great Britain.

IN the seventh Trueman Wood Lecture delivered before the Royal Society of Arts on May 21 and just published in the Society's Journal, Sir William Pope spoke on "The Outlook in Chemistry," and gave a lucid exposition of recent progress in the field of atomic structure, valency, and crystal structure.

He referred particularly to the necessity of altering the methods of teaching chemistry which seems to result from this recent work. It was suggested that a preliminary account of the manner in which all the specialised parts of chemistry fit into the general scheme of the electronic structure of matter and energy should be given. The suggestion was also made that progress in chemical discovery would be more rapid if organised research on specific problems were undertaken rather than individual work.

A FEW days ago the British Cast Iron Research Association formally took possession of its own Laboratories, in Guildford Street, Birmingham, which have been equipped for the conduct of chemical analyses and general metallurgical and heat treatment work. The capacity of the Association to deal with its work will thus be greatly increased, but it is not intended to abandon the policy of having investigations conducted in university laboratories and in the works of members. It is anticipated that the Association, which commenced a new financial year on July 1, will incur an expenditure during the year of between 6000*l.* and 7000*l.* The research programme includes investigations on erosion- and corrosion-resisting and other special cast irons; moulding sands; graphitisation; cupola practice; standardisation of test bars, materials and methods; facing sands and blackings, and cast iron to resist abrasive wear, and jointly with the British Motor and Allied Manufacturers' Research Association, automobile cylinders and pistons.

REFERENCE has already been made (May 24, p. 756) to the valuable "Handbook to the Exhibition of Pure Science" prepared by a committee of the Royal Society in connexion with the exhibits arranged by it in the Government Pavilion at Wembley. The Handbook contains, in addition to descriptions of the exhibits, a most instructive series of twenty-two articles by leading authorities upon current scientific work and problems, and every student of science should possess a copy of it. We are glad to know that arrangements have been made for its sale outside the Exhibition through Messrs. A. and F. Denny, Ltd., 163A Strand, London, W.C.2, who can supply the Handbook direct or through booksellers. The price is 1*s.*, or post free 1*s.* 3*d.*; and as the book contains 228 pages it is remarkably cheap, as well as superior to many volumes published at a much higher price, whether intended for the general public interested in science or for students in school or college.

THE annual field day at the National Fruit and Cider Institute of the University of Bristol, Long Ashton, was held on Tuesday, July 15, and was attended by a representative gathering of agriculturists and horticulturists from all parts of the West of England and even farther afield. Among those present were Lord Bledisloe, chairman of the Governing Body of the Station, and Mr. W. G. Lobjoit, Controller of Horticulture, representing the Ministry of Agriculture and Fisheries. The visitors were first given the opportunity of sampling the ciders produced during the last two seasons in the course of the Station's experimental work on cider making. These were exhibited in the new wing recently added to the cider house. The variation in the quality of ciders due to seasonal influences was markedly illustrated by comparing ciders made in 1922 and 1923 from some of the more famous vintage varieties of apples, such as Kingston Black, Cap of Liberty, and Foxwhelp, the advantage being definitely in favour of the 1922 vintage. Among other interesting features illustrated by the ciders were the effects of storage of the fruit under various conditions prior to cidermaking, the results of natural fermentation of the juice as compared with fermentation of pasteurised juice by specially selected yeasts, and the different degrees of control of fermentation obtainable by methods of racking and filtration. After sampling the ciders the visitors were conducted through the fruit plantations to inspect the various features of the experiments at present in progress. The attention of the parties was directed by guides to the numerous field investigations in progress on many subjects of importance to the fruit-growing industry.

MR. R. M. STEWART, assistant director of the Dominion Observatory at Ottawa, has been appointed director of the Observatory in succession to Dr. O. Klotz, who died in December last.

WE learn that the Radio Society of Great Britain is in touch with the Postmaster-General regarding the restrictions as regards transmissions to the dominions and foreign countries recently introduced into the experimental transmitting licences now being issued. It is hoped that an official announcement may be made at an early date.

AT the annual general meeting of the Faraday Society held on July 7, Prof. F. G. Donnan was elected to succeed Sir Robert Robertson as president. The annual report records considerable activity during the past year, the result of which is reflected in the accounts which show a deficit of 109*l.* 11*s.* 5*d.* on the year's work. Eleven meetings were held during the year, and of these four were general discussions, which have become so striking a feature of the work of the Society. The subjects of these were: (i.) "Alloys Resistant to Corrosion." (ii.) "The Physical Chemistry of the Photographic Process." (iii.) "The Electronic Theory of Valency." (iv.) "Electrode Reactions and Equilibria." The widespread appreciation in which the publications of the Society are held is indicated in the fact that the sales of Transactions and reprints amounted to nearly 900*l.*, a figure in excess of the amount received for subscriptions. It is surprising to note that the membership of this very active Society is only 432, and that consequently an appeal for a larger membership is made in the annual report. Particulars relating to the Society may be obtained from the secretary and editor, Mr. F. S. Spiers, 90 Great Russell Street, London, W.C.1.

IN commenting upon an article in NATURE of July 12 on "Artificial Daylight," a correspondent suggests that

the apparent indifference to daylight lamps is due to their excessively high prices. Our contributor, Dr. Martin, remarks that he has no knowledge of the actual cost of production, but he agrees that the average price appears to be high. Doubtless, however, an increased demand would cheapen production and result in lowered prices. The question is one with the general question of efficient lighting. To take an actual example, there are many days during the winter in which the grading and examination of such things as seeds, tea, tobacco, etc., is very difficult, if not impossible. There is no doubt that time and money are lost in this way for want of an efficient illuminant. The actual cost of a good daylight lamp would be negligible in comparison with the saving effected; that is, if the user trusted his lamp and the customer had been educated to the point of trusting it also.

THE following are among the pensions granted during the year ended March 31, 1924, and payable under the provisions of section 9 (1) of the Civil List Act, 1910: Mrs. C. A. F. Rhys Davids, in recognition of her contributions and those of her husband, the late Prof. Rhys Davids, to the advancement of Pali and Buddhist knowledge, 100*l.*; Mrs. Blanche Hartog, in recognition of the contributions of her husband, the late Prof. Marcus Hartog, to the study of natural history, 50*l.*; Dr. Alice Lee, in recognition of her services to the cause of scientific research, 70*l.*; The Misses Ethel Marian and Katherine Elizabeth Rivers, jointly and to the survivor, in recognition of the services rendered by their brother, the late Dr. W. H. R. Rivers, to the cause of anthropology, physiology, and psychology, 100*l.*; Mrs. M. F. Robertson, in recognition of the services rendered by her husband, the late Dr. W. F. Robertson, to science and medicine, 100*l.*

MR. F. EDWARDS, 83 High Street, Marylebone, has just issued Catalogue No. 460 (British Empire Series, No. 3), containing the titles of upwards of 1100 works relating to India, Burma, Ceylon, Afghanistan, Beluchistan, Malaya, and Borneo. Many of the books listed formerly belonged to the late Dr. W. Crooke, a regular contributor to NATURE.

WE have received Bulletin 212 of the Department of the Interior, Washington, entitled "Analytical Methods for Certain Metals, including Cerium, Thorium, Molybdenum, Tungsten, Radium, Uranium, Vanadium, Titanium, and Zirconium," by R. B. Moore, S. C. Lind, J. W. Marden, J. P. Bonardi, C. W. Davis, and J. E. Conley. The pamphlet is of great value and should be found useful by analysts. Many modern products (*e.g.* special steels) contain these so-called "rare" elements, and rapid and accurate methods for their estimation are required.

Our Astronomical Column.

LARGE FIREBALL.—On July 7, a few minutes after midnight, a splendid meteor was observed at various places. It appeared, however, at a time when few observers were about, and hence we are not likely to receive many accounts of it. The object gave a very vivid illumination for a few seconds and moved very slowly from a radiant very probably in Scorpio. The descriptions already to hand are not, however, sufficiently definite to allow safe deductions to be made from them. From near Dunstable, the flight of the fireball was recorded as from κ Draconis to a little below α Aurigæ. From near Ludgate Hill, London, the meteor appeared as a large ball of fire leaving a trail of white sparks. The nucleus was yellow in the central part and brilliant orange in the outer portion.

Observations of the position of the flight and its duration would be valuable. Large meteors have often been directed from Scorpio in the three months May, June, and July, the radiant point being a few degrees N.E. of the bright red star Antares.

AUGUST PERSEIDS.—This annual display of meteors has already given clear evidence of its activity. Mr. Denning, writing from Bristol, states that he observed an early Perseid this year on June 27, when the radiant was in about 356°+39°. From this point in Andromeda, the shower will move to E.N.E. through the northern region of Perseus and on between the constellations of Auriga and Camelopardalus. This stream of meteors has the longest duration of any known shower and the propriety of terming it "the Perseids" is perhaps questionable seeing that the meteors, during a portion of the shower's activity, diverge from Andromeda and other constellations.

Of late years this shower has formed some attractively abundant displays and notably so in 1921 and 1923. In the former year there was a decided maximum, the horary number reaching 250 for one observer on Aug. 12 A.M. Coulvier-Gravièr, a great French observer of meteors in the first half of the last century, thought that, after a maximum which he observed in 1848, the strength of the display declined so rapidly that it would be extinct by the year 1860. His conclusions were, however, far from being realised, and the shower continues to be visible every year with apparently the same richness as it exhibited in former times.

THE CANADIAN ECLIPSE EXPEDITION TO WALLAL 1922.—C. A. Chant and R. K. Young have just published the details of their investigation of the gravitational bending of starlight made at Wallal (Publications of Dominion Astrophys. Observ., vol. ii. No. 15).

An equatorial was taken, the general design of which is stated to resemble that of the 100-inch at Mt. Wilson. The total weight was about a ton. A guiding telescope of $4\frac{1}{2}$-inch aperture was attached to the camera, β Virginis being used for guiding. Two plates were taken for the Einstein investigation, each with 45 seconds exposure; 20 stars are shown, the magnitudes of which range from 4·3 to 9·5, but the two faintest were not used.

Full details are given of the measurement and reduction. The adopted mean shift at the sun's limb is 1·75″, exactly agreeing with Einstein's value. The separate values for measures in the x and y coordinates are 1·32″, 1·96″.

The results are insufficient to *prove* that the individual shifts follow Einstein's law (shift varies inversely as distance from sun's centre): but they group themselves fairly satisfactorily on either side of the theoretical curve.

The three separate investigations made during this eclipse all give mean results very close to Einstein's value.

Research Items.

ZENITH OF PRIMITIVE BABYLONIAN ASTRONOMY.—Prof. Reginald A. Fessenden, of Chestnut Hill, Mass., whose proposals for an archæological expedition to the Caucasus have received support from archæologists and ethnologists in the United States, including Prof. Clay of Yale, and Dr. A. Hrdlička, writes to ask whether any information is available in regard to a primitive Babylonian zenith fixed at Mt. Bakhar, near Baku. Prof. Fessenden is of the opinion that the zenith of primitive Babylonian astronomy, which goes back to a time when the Accadai (Agadi) had not yet descended from their mountain fastnesses, was fixed in the Caucasus. This area he maintains was the meeting-point of the original Babylonian and Egyptian civilisations. In support of this view he argues that the Book of the Dead was originally written in what Dr. Clay has called "Amuraic"—the early Semitic language—and that when it was translated into Egyptian, place-names were transformed and personal names mistranslated. When corrected in the light of a knowledge of the original tongue, these names reveal that the hidden land of Amen was the Caucasus Isthmus, for the road to which the Book of the Dead gave precise directions. The Egyptians and Colchians would thus be the same race, and the Isthmus the old home-land of the former. At the same time, many of the place-names in the neighbourhood of Mt. Bakhar, which antedate the Russian regime, are Babylonian, *e.g.* Schemacha, Marazi, Agadi-Kend, etc. It is therefore desirable to fix the zenith with some accuracy to determine which sites may be investigated by a preliminary expedition with most profit.

THE BLOW-GUN IN ASSAM.—In view of the frequent identity of culture between the Naga tribes and those of Indonesia, it has seemed rather surprising that while the blow-gun occurs among the latter, it should not have been found in Assam. Its occurrence is now recorded for the first time by Mr. J. H. Hutton in *Man* for July. It is found—as a toy rather than as a weapon—among the Thado Kukis, its principal use being to shoot rats. The darts are not poisoned. A similar toy is used in the Philippines; but the Karens of Burma, who appear to be related to the Nagas, employ the genuine blow-gun. The Thado type does not appear to be a degeneration, but is more probably the original form which in this area never developed. It consists of a single internode of simple bamboo, the maximum length being about two feet. It has an effective range of about twenty feet only, though a mere carry of seventy feet can be attained. Several patterns of dart are in use. In one of these, cotton is employed for the plug, although, it is interesting to note, this material does not occur in the area of distribution in Asia of the genuine weapon.

DIENTAMŒBA FRAGILIS IN A CHILD.—W. H. Taliaferro and E. R. Becker record (*Amer. Journ. Hygiene*, vol. iv., pp. 71-74, 1924) the case of a three-year-old girl, who was born in Baltimore and had never left the state of Maryland, infected with several intestinal protozoa, namely, *Dientamœba fragilis*, *Iodamœba williamsi*, *Endamœba coli*, *Trichomonas hominis* and *Giardia lamblia*. The child had never suffered from any intestinal disorder. Prolonged search failed to reveal any encysted stage of *D. fragilis*. The authors tabulate the 33 previously recorded infections with this species, the distribution of which indicates that, in common with other intestinal amœbæ of man, it is indigenous to the temperate zones as well as to the tropics.

DOUBLE EGGS.—Prof. T. H. Morgan contributes (*Scient. Monthly*, April 1924) a useful account of double eggs—twice as large as those normal for the species—which are supposed to arise from the union of two eggs. They develop into embryos twice as big as normal ones. The occurrence of these giant eggs has led to the attempt to unite two eggs by artificial means and to experiments on the fusion of blastulæ or parts of embryos. Prof. Morgan remarks that the results obtained from the study of fused eggs or embryos have not solved any of the larger problems of development, but have broadened our ideas concerning some of the possibilities of regulation between two systems each alone adjusted to produce only a single individual. He describes the recorded cases of the development of giant eggs of sea-urchins and the opportunity these have afforded for estimating the relative importance of chromatin and protoplasm in the development of hybrid larvæ. These giant eggs, the mode of origin of which is unknown, have a single nucleus with twice the normal number of chromosomes, and when fertilised develop at the normal rate. Large blastulæ and plutei are formed which have the normal number of cells, but the cells are twice the normal size. The normal egg of Sphærechinus contains, according to Baltzer, 20 chromosomes and after fertilisation 40; the fertilised giant egg contains, according to de Haan, 60-63 chromosomes, 40 of which probably come from the egg (diploid) and 20 from the sperm. An account is given of the hybrid plutei produced by fertilising giant eggs of Sphærechinus by sperm of Strongylocentrotus, and the stronger resemblance to the maternal plutei is probably due to the greater influence of the larger number of maternal chromosomes. Double-sized eggs of Ascaris and giant embryos of Lineus and of Triton arising from the fusion of two eggs are described and discussed, and reference is made to the origin of embryos which are not giants, but nevertheless apparently owe their origin to the fusion of two eggs (*e.g.* in a strain of Abraxas).

ICEBERGS IN NORTH ATLANTIC.—A descriptive account of the dangers of ice to vessels traversing the ocean between Europe and America, and the effective means taken to avert the danger, is given by Prof. R. de C. Ward, of Harvard University, in the *Monthly Weather Review* for February. A cruise, lasting fifteen days, was made on the U.S. Coast-guard cutter *Modoc*, on ice patrol duty, and the author being a meteorologist of great experience his communication is greatly enhanced. A memorial service was held at the spot where the *Titanic* sank, after collision with an iceberg in 1912, when 1500 lives were lost. The danger zone is now patrolled day and night during the ice season, the position of menacing bergs is given by radio to all passing ships, and no serious collision with ice has occurred since the patrol was inaugurated, a month after the catastrophe to the *Titanic*. Every vessel passing through the ice region, longitude 43° to 55° W., is expected to send by radio to the patrol vessel information as to any ice sighted. The U.S. Government manages the service, other nations assuming a share of the expense. Most of the bergs come from the fringe of glaciers bordering the west coast of Greenland, east of Baffin Bay, others come from the east coast of Greenland, and some start in Smith Sound. Charts are given showing the general drift of icebergs, and the drift track of an iceberg in the season of 1921 is shown, being traced from April 11 until May 12. Hunting icebergs is the business of the ice patrol, and the commanders of the vessels

employed are highly experienced. Photographs are given of several bergs. Testimony is borne to the splendid work done by officers and men, year after year, amid the dangers of ice, fog, and storm.

THE FATIGUE OF METALS.—Profs. H. F. Moore and T. M. Jasper have just published the third portion of their extensive research into the fatigue of metals as Bulletin No. 142 of the Engineering Experiment Station of the University of Illinois. On re-testing wrought specimens of iron and steel which have been subjected to many millions of stress alternations without failure, it is found that their endurance has been increased, the strengthening effect being greatest in those steels which are most hardened by cold-working. The static strength is also increased. Alternating stress above the endurance limit, on the other hand, weakens the metal, although the bad effect may be partly removed by polishing. Reversed axial stresses give an endurance limit which is only about 64 per cent. of that found by alternating bending tests, but this difference has not always been found by other investigators, and may perhaps be due to the form of test-piece employed. The authors consider that their test-piece represents the conditions likely to occur in the actual running of machines, and therefore recommend the adoption of the lower figure for reversed axial stresses. This recommendation may lead to controversy. Steels give inferior tests across the direction of rolling, as would be expected, and it is interesting to note that the cross tests are more improved by heat treatment than the longitudinal tests. It is doubtful whether soft non-ferrous metals and alloys have an endurance limit, and in order to determine this point it will be necessary to continue the tests for hundreds of millions of cycles. The authors take the view that fatigue failures do not take place by slip, but by the tearing apart of minute portions of crystals and spreading of the fissures so formed.

FIBROUS STRUCTURE IN METALLIC ELECTROLYTIC DEPOSITS.—Messrs. R. Glocke and E. Kaupp have recently carried out an X-ray examination of electrolytically deposited metals, which they describe in the *Zeitschrift für Physik* for May. They find it advantageous to use homogeneous radiations of medium wave length, the best results being produced by using an anticathode made of a metal closely following silver in the periodic system, the natural radiation of which excites the silver radiation of the photographic granules. An alloy of antimony and nickel (63 : 33), which melts at 1158°, a temperature nearly twice as high as the melting-point of pure antimony, was experimented with, and appears to be suitable; but the actual measurements were made with a silver anticathode. X-ray photographs were taken in a number of different directions through the material used, and showed that, in many cases, there was a distinct fibrous arrangement of the crystals. The axis of the elongated crystalline "fibres" is in the [011] direction in the case of copper, in the [111] or [112] direction for iron, [001] for nickel and [112] for chromium. In all cases this axis is identical with the direction of the electrolysing current, or perpendicular to the cathode surface. The crystallographic direction of the axis of the fibres depends on the composition of the solution; and, with some solutions, there is no fibrous structure, but the crystals are small and granular. It appears that the fibre axis is the direction of maximum growth velocity of the particular crystal in the electrolyte concerned. The nature of the cathode influences the structure, which is most perfectly fibrous when the cathode and the deposit are of the same metal.

DRY COOLING OF COKE IN GASWORKS PRACTICE.—Hot coke drawn from gasworks retorts is customarily cooled by contact with a stream or spray of water. At the newly erected Garston works of the Liverpool Gas Company the Sulzer system of dry cooling, now in operation at some continental works, has been tentatively applied to the coke derived from a bed of ten retorts, and the results were described at the annual meeting of the Institution of Gas Engineers. The coke so cooled is superior in appearance, higher in calorific power, and burns more freely in an open fireplace than that produced by wet quenching. The increased cost of dry cooling amounts to about 1*s.* 3½*d.* per ton of coke. Economic considerations indicate that the sale of dry coke is a sound commercial proposition provided the consumer realises the superior value of the dry fuel.

CHEMISTRY OF FATS.—A large part of the presidential address delivered by Dr. E. F. Armstrong to the Society of Chemical Industry on July 9 in Liverpool was a joint communication with Mr. John Allan dealing with our present knowledge of fats. After dealing with the composition and constitution of the natural glycerides, the authors emphasise the need for further research on the separation of certain fats which resemble one another closely in chemical composition, but differ widely in physical properties. They describe fully how the fatty acids are distributed in Nature, and indicate their possible modes of formation. They think that fats may be synthesised in plants and in animals from carbohydrates, of which the unit is one containing 18 carbon atoms in its molecule. Milk fats and certain nut oils may be built up from a simpler carbohydrate, like dextrose, the contained acids being synthesised from one another by repeated aldol condensations; and a third possible mode of synthesis is by resolution of dextrose into a C_3-unit and condensation of such units to form acids containing 12 or 18 carbon atoms.

SYNTHESIS OF METHANE FROM WATER GAS.—From work carried out in the laboratories of the South Metropolitan Gas Company and communicated to the annual meeting of the Institution of Gas Engineers, it appears that the reaction velocity of the synthesis of methane from water gas at 290° C. is increased about seventeenfold by the use of an activated catalyst, namely nickel-thoria, in place of nickel. The technical application of the process requires practically complete removal of sulphur compounds from the water gas employed, as it is found that one part of sulphur per million parts of gas effectively poisons the catalyst. Such removal and the necessary adjustment of the hydrogen to carbon monoxide ratio in the water gas can be effected smoothly and rapidly at temperatures industrially applicable, namely, about 550° C., by the passage of water gas and steam over a catalyst consisting of iron activated by chromium oxide deposited on five times its weight of pumice. Excluding the cost of this hydrogenation process, it is estimated that the net cost of production of a synthetic gas of approximate composition CH_4, 64 per cent.; H_2, 24 per cent.; N_2 12 per cent., and of calorific power 690 B.Th.U. per cubic foot, would be 10·9*d.* per therm. The cost of removing carbon dioxide appears to be the deciding factor as regards the possible establishment of the process on an industrial scale. (Cf. NATURE, June 9, 1923, vol. 111, p. 779.)

The Toronto Meeting of the British Association.

PROVISIONAL PROGRAMMES OF SECTIONS.

PROVISIONAL programmes of the Sections of the British Association for the Toronto meeting on August 6-13 have now been arranged, from which it appears that those who attend the meeting will be very fully occupied. The meeting will be noteworthy for the number of American and Canadian men of science who are presenting papers and taking part in many of the joint discussions.

We are indebted to the Recorders of the Sections for the following brief statements of important features of the work of the various Sections.

SECTION A (MATHEMATICS AND PHYSICS).

The outstanding feature of an extensive programme is the discussion which has been arranged, jointly with Section B, on crystal structure. The presidential address which Sir William Bragg will deliver on "The Analysis of Crystal Structure by X-rays" will form the introduction to this discussion, to which, among others, Prof. W. L. Bragg, Prof. S. Chapman, Dr. Shearer, Prof. Desch, and, possibly, Prof. Siegbahn (of Upsala) will contribute.

The exceptional equipment of the Toronto physical laboratory lends special interest to the paper promised by Prof. McLennan on "Recent Developments in Low Temperature Research," because the liquefaction of helium and the luminescence of solid nitrogen will be demonstrated. The United States, as well as Britain and Canada, will be well represented in the programme; the papers by Drs. Mohler and Foote on "Critical Potentials and their Interpretation," Prof. A. H. Compton on "The Quantum Theory of the Scattering of X-rays," Prof. Duane on "Secondary and Tertiary Radiation," and one by Prof. R. W. Wood may be mentioned.

Among the visitors to Canada, Prof. A. Fowler will read a paper on "The Spectra of Ionised Elements," Mr. R. H. Fowler will deal with "Mechanisms of Excitation, Ionisation, and Dissociation in Statistical Theory," and Prof. C. V. Raman will take a principal part in a discussion of the scattering of light.

There are many meteorological and geophysical papers promised, and the Section will have to subdivide in order to deal with them. Sir Napier Shaw has chosen the subject "If the Earth went Dry," and Mr. F. J. W. Whipple and Mr. L. F. Richardson, who are also going from England, will read papers. Canada itself is providing a number of meteorological papers; Sir Frederic Stupart, the Director of the Canadian Meteorological Office, has given as his subject "The Variableness of Canadian Winters." Astronomy will occupy a whole morning; papers are expected from Prof. Eddington on "Theory of Outflow of Radiation from a Star," Dr. H. H. Plaskett on "The Spectra of Nebulæ," and Dr. Silberstein on "Determination of the Curvature Radius of Space-time."

A special feature is being made of afternoon sectional lectures, of which there will be no less than three, and those of exceptional interest. Sir Ernest Rutherford will lecture on "Atomic Disintegration," Sir Richard Paget on "The Nature of Speech," and Prof. V. Bjerknes (of Bergen) on "The Forces which lift Aeroplanes." The last two will be illustrated by experiments. It is hoped to arrange short sessions of the Section at Saskatoon and Edmonton during the transcontinental excursion following the Toronto meeting. Sir Richard Paget has promised to lecture at both places.

SECTION B (CHEMISTRY).

Chemistry will be represented by a good attendance from Great Britain, and interesting meetings are expected. The president, Sir Robert Robertson, has selected "Chemistry and the State" as the subject of his address, and he will also deliver a lecture on explosives. The Section will join with Section A (Mathematics and Physics) in a discussion on crystal structure, and with Section I (Physiology) in one on vitamins, particulars of which will be found under the programmes of those sections. A morning will be devoted to a discussion on electrochemical industries, with special reference to Canada, Mr. H. Freeman dealing with Canadian hydro-electric development, Mr. D. A. Pritchard with the Canadian Salt Co.'s processes, Mr. R. L. Peek with electrolytic nickel, Mr. F. A. J. Fitzgerald with a radiant resistor furnace, and other contributors being Mr. F. A. Lidbury and Prof. F. G. Donnan.

Section C (Geology) will join in a discussion on liquid and powdered fuels, Dr. G. S. Hume reviewing the liquid fuels of Canada, Prof. G. A. Guess describing the use of powdered fuel in metallurgical plants, and Prof. W. A. Bone that of Canadian lignites. In another session, Prof. Bone will deal with the activation of nitrogen in explosions. An important discussion, in which Section A will join, is that on colloids, which will be opened by Prof. J. W. McBain with a group of papers dealing mainly with soaps, whilst Prof. W. D. Bancroft will speak on the permeability of membranes, Prof. E. F. Burton on the mutual action of electrically charged particles in solution, Prof. W. Lash Miller on the distribution of colloidal gold between two liquid phases, Prof. F. B. Kenrick on colloids in distilled water, and Prof. H. S. Taylor on adsorption from silver salt solutions by silver iodide. Visits to electrochemical works are being arranged.

SECTION C (GEOLOGY).

Ontario, one of the most important mineral-producing areas in the world, must of necessity be intensely interested in geological problems, and no gathering of men of science there could possibly avoid devoting considerable attention to that branch of science. While general topics are of interest in any or all circumstances, the industrial applications of geological knowledge are of paramount importance here. In addition, it is not without advantage that the problems confronting geologists and mining men in Canada are largely connected with the most ancient rocks of which we have any knowledge. Consequently the programme of Section C has been designed to stimulate, so far as possible, interest in both pure and applied geological science. The president, Prof. W. W. Watts, has selected as the subject of his address "Geology in the Service of Man," while subsequent speakers will emphasise particular aspects of applied geology as evidenced in Canada, and more especially in Northern Ontario. Inextricably bound up with the practical side of geology in Canada are the various problems connected with Pre-Cambrian rocks (indeed the word Pre-Cambrian is almost a household word in Ontario), and a whole session will be devoted to consideration of problems associated with these rocks in many parts of the world.

Appealing more strongly perhaps to another group of the public will be the joint discussion with the geographical section on changes of sea-level in relation to glaciation, coast-lines, etc., while a third on liquid and powdered fuels has been arranged as a joint discussion with Section B (Chemistry). This latter has had to be fixed to run concurrently with another meeting as the time available will not suffice for all the activities of the Section.

While such questions of general interest will occupy a considerable part of the sessions, the results of recent research work on more special subjects will be expounded by many authors. Mineralogy, petrology, palæontology, and stratigraphical geology will all be represented, so that every branch of geological interest will have its exponents.

As is usual in the case of Section C, excursions to places of interest round Toronto will form an important part of the programme. Three such excursions have already been settled, one being a week-end trip to the Niagara and Grimsby districts. Others will probably be fixed during the meeting, and members are advised to consult the notice boards outside the sectional rooms from time to time. On the western trip following the meeting, opportunities will be given for geologists to examine selected areas *en route*, but such areas must of necessity be determined by factors not entirely geological.

SECTION E (GEOGRAPHY).

The address by the sectional president, Prof. J. W. Gregory, will deal with "Inter-Racial Problems and White Colonisation in the Tropics." Another paper on allied problems will be on "Immigration from a Biological Point of View" by Dr. H. H. Laughlin. Many of the papers will treat of various aspects of Canadian geography, including Dr. Bell Dawson on "Tides and Currents in Canadian Waters," and Mr. E. M. Dennis, Mr. W. H. Boyd, Mr. N. Ogilvie, and Mr. W. H. Herbert on different branches of the work of the topographical survey of Canada. Dr. R. M. Anderson will speak on the status and prospects of the larger mammals of Canada.

Papers dealing with cartography and allied problems will be given by Mr. I. Bartholomew on modern developments in the construction of maps and Mr. J. B. Reynolds on the work of the Permanent Committee on Place-Names. Important papers in physical geography include "Wind, Wave, and Swell in the North Atlantic" by Dr. Vaughan Cornish, "Classification of Oceanic Islands" by Prof. W. M. Davis, and "The Glacial Anticyclone" by Prof. W. H. Hobbs. Prof. P. M. Roxby will lecture on the distribution of population in China, and Mr. Cuthbert Christy on Cape to Cairo progress.

Papers in human geography also include one on some aspects of urban growth by Mr. H. L. Seymour, and another on the influence of geographic conditions on the ancient Mediterranean religions by Miss E. C. Semple. Miss M. I. Newbigin's paper on the training of the geographer should direct attention to the notable lack of such facilities in Canada.

SECTION F (ECONOMIC SCIENCE AND STATISTICS).

The programme for the Economics Section at the Toronto meeting covers a wide and important field. Sir William Ashley's presidential address is "A Retrospect of Free Trade Doctrine." Business forecasting will be discussed by Prof. W. N. Persons, Mr. R. H. Coates, Prof. Mitchell, and Prof. H. W. Mackintosh.

The problem of population is to be dealt with in four papers from different points of view; Sir William Beveridge dealing with the fall of human fertility among the European races, and some of its reactions, Mr. Udny Yule with the population problem from the point of view of the Pearl and Reed law of growth, Prof. MacIver with civilisation and population, and Prof. Field with eugenic worth and economic value. Prof. J. E. Boyle is contributing a paper on the marketing of grain, and a film is to be shown illustrating the marketing of wheat. A discussion is to be held jointly with the Agriculture Section on diminishing returns in agriculture, and papers are to be read by Prof. C. R. Fay and Sir John Russell. Prof. A. L. Bowley will read a paper on the economic outlook in Great Britain, and the problem of unemployment prevention and insurance is to be discussed in papers by Prof. J. R. Commons and Mr. Bryce M. Stewart.

The meetings of the section will, therefore, bring together many of the leading economists of Great Britain, Canada, and the United States.

SECTION G (ENGINEERING).

The programme of the Section opens with Prof. G. W. O. Howe's presidential address entitled "One Hundred Years of Electrical Engineering." The remaining papers to be presented fall practically into two big groups: Canadian engineering problems and the strength of materials.

The first group is to be opened by Sir Henry Thornton, president of the Canadian National Railways, who will discuss railway transportation in Canada. This will be followed by a paper from Lieut.-Col. H. S. Lamb on engineering problems and traffic on the Great Lakes. Mr. J. B. Challies, director of the Water-Power and Reclamation Service, is to deal with the water-power resources of Canada. Water-power development commenced in 1895, and its possibilities may be envisaged from the fact that during the past ten years, while the population has increased 22 per cent., the water-power in use has increased nearly 100 per cent., and its use in industry 245 per cent. The total water-power of the Dominion is estimated at 18,000,000 horse-power, of which nearly 3,250,000 horse-power has been developed and 750,000 is under construction. The story will be taken up by Mr. F. A. Gaby, chief engineer of the Ontario Hydro-Electric, who will deal with the Hydro-Electric Power Commission of Ontario, and by Mr. R. S. Lea, who will discuss the possibilities of power development of the St. Lawrence River. A visit to the Niagara Fall Power Houses will be an appropriate conclusion to this part of the Section's work.

The second part of the programme will be opened by Prof. E. G. Coker with Mr. A. L. Kimball, of the General Electrical Company, Schenectady, who will describe American experiments on the optical determination of stress. Profs. H. F. Moore and T. M. Jasper, of Illinois University, will discuss the evidence for the existence of an endurance limit in metals, Prof. F. C. Lea, the effect of high temperature on the range of repetition stress for steels, and there are several other papers on related topics. The whole subject may be expected to be dealt with in two reports to be presented to the Section, one by Prof. C. F. Jenkin, on the work of the Fatigue Panel of the Aeronautical Research Committee, and another on the work of the Complex Stress Committee.

Other subjects to be dealt with by the Section include questions of public health (Mr. F. A. Dallyn), bio-aeration in sewage disposal (Mr. J. D. Watson), cobalt magnetic steels (Mr. E. A. Watson), and the future of power from fuel (Mr. E. K. Scott).

SECTION H (ANTHROPOLOGY).

Communications by anthropologists from Canada and the United States provide the greater part of the programme of the Section. Dr. F. C. Shrubsall's presidential address is entitled "Health and Physique through the Centuries." Other British contributions will include papers by Dr. A. C. Haddon on "A Suggested Arrangement of the Races of Man"; Dr. T. Ashby on "Recent Archæological Discoveries in Italy"; Mr. H. Balfour on "The Welfare of Primitive

Peoples," and also on "The Art of Stencilling in the Fiji Islands"; Mr. L. H. Dudley Buxton on "Skulls from the Valley of Mexico," and on "Physical Observations on Navajo Children." Prof. H. J. Rose's paper, "The Bride of Hades," will deal with virgin sacrifice as a fertility rite in early Greece and Rome.

Of communications by Canadian anthropologists, a number will deal with work which has been done under the Anthropological Department of the Geological Survey. Mr. Jenness deals with "The Ancient Education of a Carrier Indian"; Mr. T. F. McIlwraith with "The Potlach in Bella Coola," the result of a personal and, possibly, a unique experience; Miss E. G. Spier will analyse the "Ceremony of the First Salmon," and Mr. G. E. Rhoades will discuss "Composition in the Art of the North-west Coast Indians." From the United States Dr. A. Hrdlička will discuss the antiquity of man in America in the light of recent discoveries, with special reference to the skeletal remains recently found at Los Angeles. Mr. B. Oetteking also will give an account of the Santa Barbara skeletal remains; and Mr. Harlan I. Smith will describe "Trephined Aboriginal Skulls from Columbia and Washington." Dr. C. Wissler will deal with "The Segregation of Racial Characters in a Population," and Dr. Laughlin, of the Statistical Bureau, New York, will give an account of some racial characters emerging from the data obtained from immigrants. A joint discussion with Section J (Psychology) on "Racial Mental Differences" will be opened by Prof. W. McDougall.

Section I (Physiology).

The provisional programme arranged for the Section is the largest there has been for many years. It contains more than forty communications, covering a very wide range of subjects in physiology, biochemistry, and practical applications of these subjects to medicine.

The proceedings of the Section will open with the address of its president, Dr. H. H. Dale, on "Progress and Prospects in Chemotherapy." There are two joint discussions on the programme, one with Section B (Chemistry) and one with Section J (Psychology). The joint discussion with Section J will be on "Physiological and Psychological Factors of Muscular Efficiency in Industry," and will comprise the following papers among others: Prof. C. Lovatt Evans, "The Physiology of Muscular Contraction in Relation to Efficiency and Fatigue"; Prof. E. A. Bott, "Co-ordinate Volitional Action of Antagonistic Muscular Groups"; Prof. E. P. Cathcart, "Energy Exchange in Relation to Muscular Performance in Laboratory Investigations"; Prof. C. S. Myers, "Conceptions of Fatigue," and Prof. F. S. Lee, "Physical and Chemical Tests for Fatigue."

The joint discussion with the Chemistry Section will be entitled "Vitamins, and the Relation of Light to their Action," and the following are included in the papers to be contributed to it: Prof. J. C. Drummond, "Modern Tendencies of Vitamin Research"; Prof. H. C. Sherman, "The Quantitative Distribution and Nutritional Significance of Fat-soluble Vitamin"; Prof. Walter H. Eddy, "The Isolation of a Bios from Autolysed Yeast"; Prof. E. Mellanby (title not given); Prof. W. Lash Miller, "Bios"; and Prof. W. Steenbock, "Radiant Energy as the Anti-rachitic Factor."

Meeting at Toronto, it is appropriate that the Section should hear something of insulin, and Prof. J. J. R. Macleod and Mr. C. H. Best are, among others, dealing with this interesting subject.

Prof. J. C. Drummond is to deliver a popular lecture on "Cod-liver Oil."

There will be a large number of United States visitors at the Physiology Section.

Section J (Psychology).

The papers this year are so diverse in character that it is difficult to group them all under a few general headings. The presidential address by Prof. W. McDougall is entitled "Purposive Striving as a Fundamental Category in Psychology."

Three joint discussions have been arranged: (*a*) With Section H (Anthropology), on "Racial Mental Differences." *Speakers*—Prof. W. McDougall, Dr. C. S. Myers, and others. (*b*) With Section I (Physiology), on "Physiological and Psychological Factors of Muscular Efficiency in Industry." *Speakers*—Prof. Lovatt Evans, Prof. E. A. Bott, Prof. E. P. Cathcart, Dr. C. S. Myers, Prof. F. S. Lee. (*c*) With Section L (Education), on "Tests for Scholarships and Promotion." *Speakers*—Principal E. Barker, Prof. C. Burt, Prof. Sandiford, Prof. Whipple, and Prof. Buckingham.

A welcome feature of the programme is the important contributions of American and Canadian psychologists; for example, "The Problem of Personality," by Dr. Morton Prince, and "The Value of Mnemic Psychology for the Interpretation of Dreams and other Phenomena," by Prof. G. S. Brett, the local vice-president of the Section. A new feature is an informal conference of experimentalists on laboratory and applied researches, to be held on Saturday morning, August 9, Dr. C. S. Myers presiding, when several American, Canadian, and British representatives will exchange views.

Individual papers by British psychologists are: "The 'Self' in Cognition—Intuition, Concept, and Sensory Percept," by the Rev. F. Aveling; "Binocular Vision and Correct Ocular Muscle Balance: its Importance in Every-day Life," by Wing-Commander E. C. Clements; (1) "Psychological Theories of Laughter," (2) "Conscious and Unconscious in Psychology," by Dr. J. Drever; "Feeling and Emotion in Daily Life," by Mr. J. C. Flügel; "The Psychology of Déjà Vu," by Dr. J. T. MacCurdy; "Privileges and Limitations of Visual Imagery," by Prof. T. H. Pear; and "Shape-qualities or Relations?" by Prof. C. Spearman.

Section K (Botany).

The programme of the Section is noteworthy for the time which is to be devoted to discussions, either within the Section itself or in conjunction with other Sections. The proceedings start with a discussion on the ascent of sap and transport of food materials in trees, which will be opened by Prof. H. H. Dixon; other speakers will include Dr. O. F. Curtis, of Cornell University, Dr. D. F. MacDougal, Prof. V. H. Blackman, and Prof. J. H. Priestley. Another sectional discussion is to be on Canadian forest problems: the speakers at this meeting include Mr. D. Roy Cameron and Dr. J. M. Swaine, who will deal with forest protection in Canada from fire and insects respectively; Mr. E. H. Finlayson on Canadian silviculture, Dr. A. W. Borthwick on the cultivation outside Canada of Canadian trees, and Messrs. R. D. Craig and F. Storey on world timber supplies.

Joint discussions have been arranged with the Sections of Agriculture and Zoology respectively. At the former, the subject will be "Forest Problems," and four papers on aspects of forestry in the United States and in Canada will be contributed by Mr. J. W. Toumey, Mr. R. D. Craig, Prof. J. H. Faull, of the University of Toronto, and Mr. E. J. Zavitz. This discussion, by representatives from two of the greatest timber-producing countries of the world, should prove of great interest and importance. The

joint meeting with Section D (Zoology) will be to discuss the subject of "Species and Chromosomes." It will be opened by Prof. R. Ruggles Gates, and other speakers are Dr. H. Harrison, Prof. T. H. Morgan, of Columbia University, Mr. Julian Huxley, Miss K. Blackburn, and Mr. A. D. Peacock.

Prof. V. H. Blackman's presidential address to the Section will be entitled "Physiological Aspects of Parasitism." Of the numerous papers to be presented, it is impossible to mention more than a few. Contributions from the North American continent include papers on the "black dot" disease of potato, by Prof. B. T. Dickson; on the fluorescent pigments of the Cyanophyceæ, by Prof. F. E. Lloyd; on the distribution of potassium in plant tissues, by Miss E. S. Dowding; on the status of the biogenic law, by Prof. E. C. Jeffrey; on the growth of British Columbia trees, by Prof. A. H. Hutchinson; and on the behaviour of chloroplasts and other cell contents at low temperature, by Prof. F. J. Lewis. A number of papers will also be presented by British botanists.

SECTION L (EDUCATIONAL SCIENCE).

The Section is to open its session with a paper on the teaching of history and geography of the British Empire by Prof. G. M. Wrong, of the University of Toronto, followed by a paper on modern tendencies in the teaching of geography, by Mr. Ernest Young. The presentation of the Report of the special committee appointed last year to inquire into the educational training of boys and girls in secondary schools for life overseas will be followed by a discussion on the subject to be opened by Sir John Russell.

On the second day Principal Ernest Barker will deliver his presidential address, the subject being the "Nature and Conditions of Academic Freedom in Universities." Mr. A. E. Heath, of the University of Liverpool, will follow with a paper on "Modern Developments in the Method and Scope of Adult Education." A joint discussion with Section J (Psychology) on the subject of "Tests for Scholarships and Promotions" will occupy the third morning; the chief speakers will be Principal Barker, Prof. Cyril Burt, Prof. G. M. Whipple, Prof. B. R. Buckingham, and Prof. Sandiford. The latter in conjunction with Messrs. Brennan and Holmes will also contribute a paper on "The Use of Partial Coefficients of Correlation in Educational Research."

A discussion on "Modern Developments in Science Teaching" is to be opened by Mr. C. M. Stuart, late headmaster of St. Dunstan's School, Catford. Prof. J. L. Myres will read a paper on the place of classics in a secondary school system, to be followed by Mr. A. H. Hope, headmaster of Roan School, Greenwich, on the present position of classics in French secondary schools. The fourth morning will be devoted specially to subjects of Canadian interests. Sir Robert Falconer, president of the University of Toronto, will read a paper on "The Canadian University"; the Hon. Dr. H. J. Cody on the administration of education in Canada; Prof. G. M. Weir on an educational experiment in rural Saskatchewan; Dr. S. B. Sinclair on the selection of pupils for auxiliary classes; and Major J. B. Cowles on the working of the Adolescent Education Act in Ontario.

SECTION M (AGRICULTURE).

The meetings of Section M will be held under the presidency of Sir John Russell, the director of the Rothamsted Experiment Station, whose address on "Combination in tackling Farmers' Problems" will be given on Monday, August 10.

The proceedings on Thursday, August 7, will be opened by a short address by the Hon. J. S. Martin, Minister of Agriculture for the Province of Ontario. He will be followed by Dr. F. T. Shutt on "The Influence of Cropping on the Nitrogen and Organic Matter Content of Western Prairie Soils." Mr. H. J. Page, the head of the Chemical Department at Rothamsted, will read a paper on "Nitrogen Balance in the Soil"; and he will be followed by Dr. Scott Robertson on "The Fertilising Effect of Rock Phosphate." The next morning will be occupied by a joint discussion with Section D (Zoology) on "The Soil Population." This will be opened by Mr. D. Ward Cutler. In the afternoon, Mr. J. B. Reynolds, the principal of the Guelph Agricultural College, will speak on "Agricultural Colleges in Canada."

On Saturday, August 9, Mr. R. A. Fisher, of Rothamsted, will read a paper on "The Incidence of Rainfall in Relation to the Wheat Crop," and later in the morning Dr. McRostie will speak on "Forage Crops in Canada." The same day, Mr. Engledow will read a paper on "A Spacing Experiment with Wheat," which will terminate the day's proceedings.

On Monday, August 11, Mr. Godden will speak on the work which is being carried out at the Rowett Research Institute on the mineral requirements of farm animals, and Prof. Berry will follow with a paper on "The Chemistry of the Oat Crop." The afternoon will be occupied by a joint meeting with Section K (Botany) on "Forest Problems in Canada," to which Mr. Zavitz and Dr. Faull are contributing.

On Tuesday, August 12, the whole morning will be devoted to a joint meeting with Section F (Economics), the subject for discussion being "Diminishing Returns in Agriculture." This discussion will be opened by Dr. C. R. Fay, and it is hoped that other speakers will include Sir John Russell, Lord Bledisloe, Sir Henry Rew, and Mr. Ashby.

The proceedings of the Section will conclude with a joint meeting on forestry with Section K, in which such subjects as forest protection in Canada, and the cultivation of Canadian trees in other parts of the world, will be brought forward.

After the conclusion of the meeting, several local excursions have been arranged, including a visit to the Agricultural College at Guelph.

Atoms and Ethereal Radiations.[1]

IN his first lecture the speaker, after outlining the steps by which he and his collaborators had succeeded in pushing the region of wave-lengths explored by mechanically ruled gratings down to 136 Ångströms, presented the results which had very recently been obtained by Mr. I. S. Bowen and himself, through the analysis, with the use of high resolution, of the fine structure of these extreme ultra-violet lines.

Photographs were shown in which such a close doublet as the B_{III} line at 677 Ångströms was not only clearly resolved, but had its components so well separated that their distance apart, which amounted to but 0·15 Ångströms, could be measured with certainty to 0·01 Ångströms or better, and in which the seven components of the 834·0 line of oxygen were

[1] Abstract, prepared by the author, of three lectures delivered on June 16, 17, and 18, at University College, London, by Robert A. Millikan, Director of the Norman Bridge Laboratory of Physics of the California Institute, Pasadena, entitled (1) "Filling in the Gap between X-rays and Light"; (2) "Electronic Orbits in Atoms"; (3) "The Penetrating Radiations of the Upper Air."

clearly obtained in orders as high as the seventh. This high resolution has made it possible for Mr. Bowen and the author to prove with certainty that in their "hot-sparks" in high vacua, they have succeeded in stripping all of the valence electrons from the series of atoms, lithium, beryllium, boron, carbon, nitrogen and sodium, magnesium, aluminium, silicon, phosphorus, sulphur, six electrons having been removed from the outer shell in the case of the atom of sulphur.

As an illustration of the way in which this can be proved, as well as of the way in which the recently discovered laws of atomic mechanics can be beautifully verified, the lecturer took the case of the stripped boron atom B_{III}, the spectrum of which had not before been known. Mr. Bowen and he first predicted that if they had B_{III} in their source they should have a line at 2077·4 Ångströms. They arrived at this figure by dividing the corresponding line of lithium ($3d$-$4f$) by nine. They then set their spectrograph for this wave-length and obtained the predicted line—quite a strong one—at the accurately measured wave-length of 2077·79 Ångströms. They next predicted a line ($4f$-$5f$) at 4500 Ångströms, and obtained it at 4499 Ångströms, or within one part in 5000 of the predicted wave-length. They next predicted two doublets ($2p$-$3d$) and ($2p$-$3s$), of the same frequency separation at 677 and 758 Ångströms, and found both of them in the positions predicted and with the same frequency separation precisely as their theory demanded, this separation agreeing, too, as it should, with that of the first line of the principal series of B_{III} ($2p$-$2s$) first accurately measured in this work. Photographs showing all these lines as doublets, with the correct separation, were shown.

The speaker concluded his first lecture with the presentation of the proof, furnished by his slides, that the Moseley law of progression of frequencies with atomic number, discovered through the study of X-ray spectra, holds also in the region of optical wave-lengths, such as he has been studying with the aid of his mechanically ruled gratings. In particular he showed that the L_I levels of sodium, magnesium, and aluminium obtained from his "hot sparks" fall, along with that of neon, very accurately upon a Moseley line; also that the strongest L line of the foregoing elements can be plotted upon the same straight line with the corresponding lines obtained by Siegbahn with the elements down to copper; and that a like type of progression was found in the L spectra of the elements from neon down to lithium.

Thus, though the wave-lengths between the lecturer's lower limit of 136 Ångströms reached by grating spectroscopy, and Siegbahn's upper limit of 18 Ångströms, reached by crystal spectroscopy, had not thus far been directly obtained, yet this small remaining gap has been bridged over by the establishment of a common law, with the aid of which it is now possible to compute with certainty some of the most outstanding characteristics of the radiations which must fall in the as yet unexplored region. To this extent then, the gap between X-rays and light has already been completely bridged.

In his second lecture the speaker presented, in a series of tables, work of Mr. Bowen and himself, as yet unpublished, in which two other X-ray laws, namely, the *regular*, or relativity-doublet law, and the *irregular* doublet law were definitely extended throughout the whole field of optics. This extension has become possible because the foregoing series of stripped atoms gives the first opportunity to compare, *in the field of optics*, a fairly long series of atoms possessing exactly the same electronic structure, but in which the nuclear charge progresses by unitary steps. It is in general such a series of identical electronic structures which is dealt with in comparing X-ray spectra. Hence the possibility of a very precise comparison o atomic behaviour in the optical and the X-ray regions

The definite extension by Mr. Bowen and th lecturer of the X-ray laws into the field of optic means unquestionably, to take a simple specific case that in the second quantum state the so-called 2 terms in optics correspond exactly to the L_I term in X-rays, the $2p_2$ terms in optics to the L_{II} term in X-rays, and the $2p_1$ terms in optics to the L_{II} terms in X-rays. Stated otherwise, if the L_{II} and L_{II} levels in X-rays represent a relativity doublet, a they have hitherto been supposed to do, and corre spond therefore to two differently shaped electroni orbits, one a circle $[2_2]$, and one an ellipse $[2_1]$, the p_2 and p_1 in optics also represent a relativity doublet and correspond to these same two orbits.

While from an experimental point of view thi definite unification of optics and X-rays under a common set of laws (Moseley law, relativity-double law, irregular doublet law) must be regarded as a distinct step in advance, since it tends toward a simplification, for the purposes of prediction, of th whole subject, it nevertheless introduces a very seriou difficulty into the present status of atomic theory For it appears to force us to choose between tw positions, either of which presents apparently in superable obstacles.

If we retain the physical interpretation of th relativity-doublet formula—a formula which i derived without the introduction of any arbitrary constant whatever from the theory of the change in mass with speed, and has had *quantitative* successes in interpreting the whole fine structure of the lines of atomic hydrogen and ionised helium—we must discard very largely the interpenetrating-orbit ideas with the aid of which Bohr and other workers have recently interpreted so successfully both optical and chemical phenomena. Specifically the difference between the energies of the so-called s and the p terms in optics can no longer be interpreted as due to the difference in the shapes of the $2s$ and the $2p$ orbits, the $2s$ corresponding to an ellipse, and the $2p_2$ and $2p_1$ to two circles. For if the relativity doublet interpretation is applied to the levels $2p_2$ and $2p_1$, one of these levels, namely $2p_2$, must correspond to an ellipse, while the other, $2p_1$, corresponds to a circle. *This requires that 2s and $2p_2$ be orbits of the same shape, namely, 2_1 orbits, despite their large difference in energy.*

If, on the other hand, we retain the assignment of azimuthal and inner quantum numbers which has been universally made in recent years in the field of optics, and hence make the $2p_2$ and $2p_1$ levels correspond to two circles which differ slightly in energy because of a difference in orientation (inner quantum numbers), we are forced by the results herewith presented to treat L_{II} and L_{III} in the same way. This requires us to find some other cause than change of mass with speed to account for their observed difference in energy, which is, however, quantitatively accounted for by this so-called relativity-doublet theory.

Before the accumulation of the present data it was not so difficult as it is now to discard the relativity-doublet interpretation, but in this data the relativity-doublet formula has had new successes, for it fits satisfactorily with the behaviour of a whole group of atoms which pass over in successive stages toward the structure of atomic hydrogen and ionised helium. Thus there now seems to be no place to stop in discarding the relativity-doublet explanation short of abandoning *in toto* the idea of change of mass with speed in electronic orbits, and assuming that it was mere chance which caused this conception to lead to a formula which has had amazing successes, not

only in predicting exactly the fine structure of the hydrogen and helium lines, but also in explaining very beautifully the complexities of the Stark effect in these gases.

Such an assumption of accidental agreement where the relations are so beautifully quantitative and so numerous as they are here is one which the theoretical physicist will be very loath to make. The lecturer felt that further experimental data must be accumulated before a choice could with certainty be made between his alternatives. The present experimental situation, so far as the work of Mr. Bowen and himself are concerned, will be presented fully in forthcoming articles in the *Physical Review*.

In his lecture on the "Penetrating Radiation of the Upper Air," the results of the experiments made by Mr. Bowen and the lecturer at Kelly Field, Texas, were described. They sent up sounding balloons carrying recording electroscopes, thermometers, and barometers to a height nearly twice as great (about 16 km.) as that reached in preceding studies of the penetrating radiation. The total weight of the whole apparatus sent up, exclusive of the balloons, was but 180 grams. The electroscope chamber consisted of an hermetically sealed, steel-walled vessel of about 200 cc. capacity, containing air at varying pressures ranging from 1 up to 11 atmospheres. Four such instruments had been sent up and three recovered, two of which had reached altitudes between 15 and 16 km., and both agreed in giving the integrated ionisation not more than 25 per cent. of that obtained by extrapolation from Kolhörster's curves or computed from his 1914 absorption coefficient $\mu/D = 5{\cdot}77 \times 10^{-3}$ cm.^{2}/gm. These results showed quite definitely that no external source of radiation having the postulated characteristics existed. At the same time, they showed that the balloons in their ascent passed through regions in which the penetrating radiation was greater than its value at the earth's surface, since the integrated leak could not otherwise be greater than its value at the surface.

Dr. Russel Otis, of the California Institute at Pasadena, then checked these results by observations made in a number of aeroplane flights up to altitudes of 17,000 ft. In these flights he calibrated his electroscope at each particular level, thus rendering his results quite independent of any possible effects of temperature and pressure. He found, in agreement with Kolhörster, Hess, and others, that the penetrating radiation decreases slightly up to altitudes of six or eight thousand feet and then begins to increase. The actual values at 17,000 ft. (5·18 km.) were, however, but half those reported by Kolhörster at this altitude. Observations which Dr. Otis then made on Mt. Whitney at altitudes up to 13,000 ft. checked quite well with those made in aeroplanes, thus indicating that the phenomenon is one due to altitude rather than to locality.

The most conclusive evidence as to the source of the radiation has come from a continuous series of night and day observations, inside and outside 5 cm. thick lead screens, which the lecturer and Dr. Otis carried out last September on the top of Pikes Peak (14,100 ft.) in Colorado. During these observations, as a result of a snowstorm, the ionisation inside the closed observing chamber dropped suddenly about 10 per cent., but when the test was made inside the chamber *when it was completely shielded by its 5 cm. of lead*, the percentage fall in the ionisation was about the same as in the unshielded chamber, thus indicating that *local causes* modified the ionisation which got through 5 cm. of lead as much as they modified that which did not have to go through such a screen. If a very penetrating radiation of cosmical origin existed, this should have been completely unmodified by local changes, so that the percentage change inside the shielded vessel should have been very much less than that observed when the shields were removed. This observation was, then, an indication that the whole of the radiation measured in the closed vessel was of local origin.

This indication was confirmed as follows: assuming, following Kolhörster's 1923 conclusions, a penetrating radiation of cosmic origin which produces 2 ions/cc./sec. at sea-level, and has an absorption coefficient per cm. in water of $\alpha = 2{\cdot}5 \times 10^{-3}$, we find that this radiation would produce 6 ions/cc./sec. on top of Pikes Peak and 5·2 inside our lead shield. We found that the ionisation in our chamber contributed by the walls and the lead shields was at least 7 ions, so that if there were no local radiation at all on Pikes Peak capable of getting through our screens, a condition contrary to fact, the lowest obtainable value of the ionisation inside our vessel should have been $7 + 5{\cdot}2 = 12{\cdot}2$ ions. *We observed directly 11 ions.* We conclude, therefore, that there can exist no such penetrating radiation as we have assumed.

Our observations, therefore, seem to us to show that the whole of the penetrating radiation on top of Pikes Peak is of local origin. We have computed its absorption coefficient and find it but a little harder than that of the ordinary radioactive materials. How such quantities of radioactive material get into the upper atmosphere is as yet unknown.

University and Educational Intelligence.

BELFAST.—At the meeting of Senate of the Queen's University held on July 16, a letter was read from the trustees of the late J. C. White intimating that they intended to hand over to the University a sum of 60,000*l*. Of this amount (1) a sum of 45,000*l*. is to be used in founding a professorship of biochemistry with a salary of 800*l*. per annum and equipping the department. (2) The remaining 15,000*l*. is to be used in founding a lectureship in bacteriology with a salary of 450*l*. and equipping the department. The title of the professorship is to be the "J. C. White Professorship of Bio-chemistry," and the title of the lectureship the "J. C. White Lectureship in Bacteriology."

On July 17 the cheque for 60,000*l*. was handed to the honorary treasurer of the University.

CAMBRIDGE.—The Local Lectures summer meeting will be held on August 1-21, and an attractive programme has been issued. The chief subject of study will be Egypt, its ancient, medieval, and modern aspects, and among the lecturers who have been secured are Sir Flinders Petrie, Prof. A. S. Hunt, Dr. A. H. Gardiner, Dr. A. M. Blackman, Dr. W. F. Hume, and Sir William Willcocks. The group of lecturers on science include many of the leading scientific workers in the University, with the addition of Dr. Leonard Hill, director of the Department of Applied Physiology, Medical Research Committee, Prof. H. H. Turner of Oxford, and Dr. A. E. H. Tutton. The inaugural address to the meeting will be delivered by Viscount Haldane. Further information can be obtained by application to Dr. Cranage, Syndicate Buildings, Cambridge; letters should be endorsed "Summer Meeting."

EDINBURGH.—The following doctorates were conferred at the Graduation Ceremony on July 17, the subject of the thesis in each case following the name:—*D.Sc.*: Mr. T. M. Finlay, "The Old Red Sandstone of Shetland"; Dr. R. K. S. Lim, "Gastric

Secretion"; Mr. G. P. Douglas, "The Effect of High Tip Speeds on the Performance of Aeroplane Propellers"; D. Penman, (*a*) "Investigations relating to Temperature Conditions in Indian Mines and to the Explosibility of Indian Coal Dusts"; (*b*) Development of a Simplified View of Mine Ventilating Resistances, with Supplementary Papers." *Ph.D.*: Mr. R. T. Dunbar, "Experiments on the Absorption of X-radiation of Short Wave-length, and on the Associated Scattered and Corpuscular Radiation"; Mr. D. A. W. Fairweather, "The Electrolysis of Salts of Alkyloxyacids"; Honor Bridget Fell, "Histological Studies on the Gonads of the Fowl"; Mr. R. E. Gibson, "The Electrolysis of a Mixture of the Potassium Salts of Acetic and Trichloracetic Acids and on the Nature of Kolbe's Electrosynthesis and Allied Reactions"; Mr. J. Haldane, "The Action of Diphenylformamidine on the Phenols"; Mr. J. H. Kenneth, "An Experimental Study of Effects and Associations due to Certain Odours"; Satis Ranjan Khastgir, "The Scattering of X-Rays and the J-Absorption Phenomenon"; Christina Cruickshank Miller, "Diffusion in Solution"; Mr. T. R. Paterson, "The Influence of Substitution on the Velocity of Reaction between Benzoic Anhydride and an Aliphatic Alcohol"; Mr. W. Robson, (*a*) "The Metabolism of Tryptophane—the Synthesis of Bz-3-Methyltryptophane; (*b*) "The Influence of Insulin on Acidosis and Lipæmia in Diabetes"; Mr. R. H. Slater, "The Influence of the Nature and Position of Atoms in Organic Compounds on the Reactivity of other Atoms in the Molecule. Polarity Effects in Aromatic Halogen Compounds"; Mr. C. M. Yonge, "The Mechanism of Feeding, Digestion, and Assimilation in *Nephrops norvegicus*."

A Diploma in Technical Chemistry is now granted by the University to graduates of British or other approved universities who have taken a degree in science with honours in chemistry. The course of study for the Diploma extends over one academic year, and comprises instruction not only in technical chemistry but also in the elements of engineering practice, and in factory organisation and factory accounting.

Dr. D. Murray Lyon has been appointed Christison professor of therapeutics, in succession to Prof. J. C. Meakins.

Lieut.-Col. E. D. W. Greig has been appointed lecturer in tropical diseases. Lieut.-Col. Greig was formerly Director of Medical Research in India.

Among the recipients of the honorary degree of Doctor of Laws on July 17 were the following: Mrs. Sidney Webb; Mr. F. R. Jamieson, Senior Inspector of Schools; Sir David O. Masson, professor of chemistry at Melbourne; Prof. C. J. Martin, Director of the Lister Institute of Preventive Medicine; Prof. S. J. Hickson, of Manchester; Mr. G. G. Chisholm, formerly reader in geography at the University.

Dr. D. P. D. Wilkie, lecturer in clinical surgery, has been appointed to the chair of surgery for a period of ten years.

GLASGOW.—Mr. Hector J. W. Hetherington, principal of the University College of the South-West of England, Exeter, has been appointed to the chair of moral philosophy, in succession to Prof. Lindsay, now the Master of Balliol.

LEEDS.—Prof. J. B. Baillie, professor of moral philosophy in the University of Aberdeen, has been appointed Vice-Chancellor of the University, in succession to Sir Michael Sadler. Prof. Baillie was educated at Edinburgh, Trinity College, Cambridge, Halle, Strasbourg, and Paris.

MANCHESTER.—Mr. E. A. Milne, assistant director of the Solar Physics Observatory at Cambridge, has been appointed to the Beyer chair of applied mathematics.

ST. ANDREWS.—A letter was read from Prof. A. E. Taylor resigning the chair of moral philosophy in the University on his appointment to the chair of moral philosophy in the University of Edinburgh. The Court resolved to tender their congratulations to Prof. Taylor on his appointment, and to express their appreciation of the good fortune which has enabled this University to enjoy the benefits of his scholarship and share in his reputation for a fruitful period of sixteen years.

It was unanimously agreed to invite Mr. David Morrison, lecturer in logic in the United College, St. Andrews, and in University College, Dundee, to accept the vacant professorship as from October 1 next.

The Court resolved to appoint Dr. G. McOwan, assistant to the professor of chemistry, St. Andrews, to be lecturer in organic chemistry in the United College in succession to Dr. A. K. Macbeth, resigned. It was intimated that Mr. J. Stirling had resigned the post of assistant to the lecturer in botany in the United College, St. Andrews, on his appointment to a junior lectureship in the University of Liverpool. The Court approved the appointment of Mr. J. Duke Stewart as a tutor in anæsthetics in the University.

THE vacant principalship of the Northampton Polytechnic Institute, Clerkenwell, caused by the tragic death of Dr. R. Mullineux Walmsley in June, has been filled by the appointment of Mr. S. C. Laws, principal of the Wigan Mining and Technical College for the past nine years. The appointment is subject to the approval of the London County Council. Mr. Laws was educated at University College, Nottingham, and St. John's College, Cambridge, where he attended as an 1851 Exhibition research scholar and was admitted as an advanced student. He worked at Cambridge at the Cavendish Laboratory under Sir J. J. Thomson and received the special distinction of an extension of his scholarship for a third year, the University of Cambridge awarding him the certificate for distinguished research.

THE Universities' Library for Central Europe, established four years ago under the presidency of the late Viscount Bryce to meet the book-famine in the universities of central European countries, is appealing for funds to enable it to continue its work for at least another twelve months, after which it is anticipated that the economic conditions of those countries will have improved so as to render such external help less needful. The report of the executive committee for the two years 1922–24 shows that during that time 14,000 volumes and 25,000 periodicals were received by gift, and more than 1500 volumes by purchase. The presentations included several sets of NATURE and other journals. The number of consignments despatched were: To Austria 22, Czecho-Slovakia 37, Danzig 4, Finland 10, Germany 64, Hungary 10, Poland 19, Roumania 3, Russia 34. Among the subsidiary activities of the organisation may be mentioned: co-operation with the Vienna International Summer School and with the British Committee for aiding men of letters and science in Russia, and despatching French books to Paris for villages in the devastated areas. The honorary secretary is Mr. B. M. Headicar, of the London School of Economics. Contributions, which may be earmarked for any particular country or university, should be sent to Sir George S. Gibb, London School of Economics, Houghton Street, London, W.C.2.

Early Science at the Royal Society.

July 27, 1664. Ordered, That at the first opportunity Mr. Hooke be put to the scrutiny for the place of curator: That he forthwith provide himself of a lodging in or near Gresham College: And that these orders and votes be kept secret, till Sir John Cutler shall have established Mr. Hooke as professor of the histories of trades.

1681. The President [Wren], Mr. Henshaw, Mr. Colwall, Dr. Gale, Dr. Croune, Dr. King and Mr. Hooke were appointed a committee to go to Chelsea, and to meet at the Swan-tavern there at nine in the morning to speak with the Lord Cheney about inclosing the ground of Chelsea-college next the meadows.

July 28, 1670. The society thinking proper to discontinue their public weekly meetings, there was recommended to Mr. Hooke during this recess the care of these three things: 1. To continue to observe, whether there be a parallax in the earth's orb. 2. To observe the present variation of the needle. 3. To measure the quantity of a degree upon the earth.

1686. There happened much discourse about the way of preserving ships from the worms; and it was remarked, that sheathing with lead was the best expedient, and found to be so by the experience of Sir Anthony Deane; but that the carpenters opposed it as against their profit, affirming that the iron of the rudders so sheathed was more apt to be corroded.

July 30, 1663. Christopher Wren to the president [Viscount Brouncker]—"The act and noise of Oxford being over, I retired to myself as speedily as I could, to obey your lordship, and contribute something to the collection of experiments designed by the society for his majesty's reception. The solemnity of the occasion, and my solicitude for the honour of the society, make me think nothing proper, nothing remarkable enough. It is not every year will produce such a master experiment as the Torricellian, and so fruitful as that is, of new experiments; and therefore the society hath deservedly spent much time upon that and its offspring. To produce knacks only, and things to raise wonder, such as Kircher, Schottus, and even jugglers abound with, scarce become the gravity of the occasion. It must therefore be something between both, luciferous in philosophy, and yet whose use and advantage is obvious without a lecture. . . . It is upon billiards and tennis-balls, upon the purling of sticks and tops, upon a vial of water, or a wedge of glass, that the great Des Cartes hath built the most refined accurate theories that human wit ever reached to. For myself, I must profess freely I have not anything by me suitable to the idea I have of what ought to be performed upon this occasion. . . .

1668. The experiment of shutting up two finches in two glasses of different capacity was tried. The vessels were closed with very good cement, the one containing about four and a half times the liquor of the other. The birds were both put in at the time of fifty-five minutes past four. That in the smaller glass appearing ready to die, after nineteen minutes, was taken out, but found dead. The other was kept in about an hour and twenty-eight minutes, and appearing to be sick, though not so very much so, was taken out, it being time for the society to rise; whereby it seemed, that the times and the quantities of the air necessary for respiration in these birds were almost in reciprocal proportion to one another.

August 1, 1678. Some mention was made of cures done by the natural heat of living bodies outwardly applied. Sir Christopher Wren observed, that the raising of a blister would cure the stinging of wasps. . . .

Societies and Academies.

LONDON.

Geological Society, June 25.—Dr. J. W. Evans, president, in the chair.—Miss M. E. **Tomlinson**: The river-deposits of the lower valley of the Warwickshire Avon; with an appendix by A. S. **Kennard** and B. B. **Woodward.** Fluviatile sands and gravels occur as river-terraces between Stratford and Tewkesbury. The surfaces of these terraces lie on curves parallel to the present thalweg of the Avon. Five such terraces have been identified. No. 5 Terrace, the highest above river-level, has yielded no contemporaneous fossils. No. 4 and No. 3 both contain a warm fauna, with Hippopotamus and *Belgrandia marginata* occurring solely at No. 3 level, and *Corbicula fluminalis* at No. 4 level. No. 2 contains a cold fauna, with numerous remains of mammoth and *Rhinoceros tichorhinus*. No. 1 probably underlies the alluvium, and may be connected with the infilling of the buried channel which has been identified at Fladbury and Tewkesbury. The sole evidence of human industry found is a fresh flint of Mousterian type from No. 2 Terrace.—F. **Raw**: The development of *Leptoplastus salteri* Callaway, and of other trilobites (Olenidæ, Ptychoparidæ, Conocoryphidæ, Paradoxidæ, Phacopidæ, and Mesonacidæ). *Leptoplastus salteri* occurs in the Upper Tremadoc horizon of Shineton Brook (Salop). All stages of development are noted, except the protaspis. The development is divided into successive stages. The earliest stage has a long, simply segmented glabella; long pleural spines occur throughout the body, including three pairs on the head and four on the pygidium; while axial spines occur from the occipital segment throughout. In the last stage the glabella is short, conical, and smooth; of pleural spines, only the genal remain on the head, those in the thorax are reduced, and none remain on the pygidium, where axial spines are also wanting. With certain reservations, these four stages are also claimed to represent successive stages in the phylogeny. This ontogeny sheds much light on that of other trilobites. In the ontogenies of several families, it is the primitively posterior head-spines that at first are dominant—to be superseded later by the middle pair. In Mesonacidæ these again are succeeded by the anterior pair, which, in their lateral revolution, carried before them the anterior branches of the facial sutures, so that these cut the posterior border; they also stretched out the antero-marginal suture to the genal angle. These changes led to the supersession of the dorsal facial suture by the marginal suture, with consequent ankylosis along the former. The family is hereby claimed to have a head-structure not hitherto recognised. It illustrates a general principle—that those only of the cephalic sutures are retained as were necessary for ecdysis. The combined study of trilobite ontogeny and morphology strongly suggests, as Beecher claimed, that here the ontogeny extensively recapitulates the phylogeny; and therefore best indicates relationships. This indicates an early divergence in glabella-form, antedating divergences in cephalic spines and sutures. Members of a "natural" order may, therefore, be expected to agree much more in glabella-form than in the cephalic suture, which has latterly been made the basis of classification.

Physical Society, June 27.—Mr. F. E. Smith in the chair.—O. W. **Richardson**: Thermionic emission from systems with multiple thresholds. The question of the connexion between thermionic emission and the internal electron levels of the emitting substance must be faced. The theoretical problem is attacked from

three different points of view, namely, (*a*) classical statistical mechanics, (*b*) chemical dynamics, and (*c*) the laws of photo-electric action. As a result it seems possible to exclude certain alternatives which might otherwise have appeared not improbable and to formulate a set of rules governing the fundamental phenomena which are not in conflict either with the known facts or with any well-recognised relevant principle.—F. C. **Toy**: A selenium photometer. The instrument was designed for use by photographic manufacturers in measuring the density of a negative after test exposures which vary from strip to strip of the negative. By means of a selenium cell, the intensities of two beams of light are compared, one of which passes through the part of the negative to be tested while the other passes through a compensating wedge which has to be adjusted until its effect on the second beam is equal to that of the negative on the first beam. As one beam is progressively obscured by one shutter, the other is progressively opened, the total illumination of the selenium cell remaining constant provided that the two beams on reaching it are of equal intensity. The method is extremely accurate.—L. **Hartshorn**: A method of measuring very small capacities. A bridge arrangement is described suitable for the measurement of very small capacities (of the order of 1 micro-microfarad and less) at telephonic frequencies. Means of securing (1) great sensitivity, (2) fineness of adjustment, and (3) elimination of capacities to earth and capacities due to the presence of connecting leads, are indicated, so that it is possible to measure the true inter-capacity between any two conductors, *e.g.* the electrodes of a thermionic valve. As a test of the method, it is used to measure the capacity between two steel balls of 1 cm. radius and at distances apart of 2·25 to 8 cm.—E. **Wilson**: A new form of string galvanometer. The magnets consist of two rings of cobalt chrome steel of 25 cm. diameter, the cross-section of the bar being 5 cm. × 1 cm. Each ring has an air gap of 0·1 cm., and the poles have a bevel of 45°, terminating in opposing faces of 0·4 cm. wide. The magnets are mounted one above the other, with their gaps in line, and a separation between the rings of 1 cm. The strings, two in number, are of platinum wire 0·002 cm. diameter, and are supported symmetrically in the gap by a brass former, the effective length of each string being 10 cm. —W. E. **Curtis**: The phosphorescence of fused transparent silica. A mercury lamp and a hydrogen tube, both of transparent silica, were used. Heat increases the intensity of the phosphorescence and decreases its duration. With helium containing a trace of hydrogen, it was found that whereas a condensed (oscillatory) discharge gave the Balmer lines faintly and feeble phosphorescence, an uncondensed (unidirectional) discharge developed neither Balmer lines nor phosphorescence. There was also a correspondence between the localisation of the Balmer lines and that of the phosphorescence. On admitting hydrogen to the helium tube by making it red hot, the phosphorescence was obtained strongly. The effect may be due to radiation of wave-lengths occurring in the hydrogen spectrum, but absent from the helium spectrum; the Lyman series of hydrogen, which lies between λλ 1,215-912 A, is probably the effective radiation.

Aristotelian Society, July 7.—Prof. T. P. Nunn, president, in the chair.—H. Wildon **Carr**: The scientific approach to philosophy. There are two problems of philosophy which are fundamental in their relation to present scientific research. The first concerns the biological sciences. It is the problem of the nature and genesis of the human intellect, whether it is essentially a cognitive faculty of receiving a revelation of reality by simple contemplation and natural reasoning, or whether it is a mode of cognitive activity produced in the evolution of life for a vital purpose, that is, to serve a special form of living activity. The second problem concerns the subject-matter of mathematics and physics. It is the problem of the subjective conditions of sense experience imposed on the observer of Nature, how far they must be held to qualify the objectivity of the results of observation and in what way they can be allowed for or abstracted from. Neither of these problems can be ignored by the scientific researcher, and both carry science beyond the realms of physics and biology into metaphysics and philosophy. The first is the leading motive in the philosophy of Bergson. The second is being forced on the attention of philosophers by the new principle of relativity of Einstein.

DUBLIN.

Royal Irish Academy, June 23.—Prof. Sydney Young, president, in the chair.—K. C. **Bailey** and Mrs. D. F. H. **Bailey**: The colorimetric estimation of thiocyanates and cyanates. The tests proposed by Spacu and by E. A. Werner for the detection of thiocyanates and cyanates respectively by the formation of coloured compounds with copper and pyridine are adapted to the colorimetric estimation of these substances. The estimation can be successfully performed in the presence of most common acids, bases and salts. Cyanates can be estimated thus in the presence of urea, but thiourea interferes with the estimation of thiocyanates.—J. J. **Dowling** and J. A. C. **Teegan**: Optical interference experiments with multiple sources. By the use of a train of two or more biprisms, multiple images of an illuminated slit are obtained. The resultant interference pattern has been observed corresponding to light sources arranged in any symmetrical formation. The fact that these sources do not lie in one plane introduces difficulties.

Royal Dublin Society, June 24.—Prof. J. A. Scott in the chair.—H. H. **Dixon**: Variations in the permeability of leaf-cells. With suitable arrangements, large changes in the electrical resistance of leaf-tissues may be shown to be associated with changes of temperature. Thus it may be inferred that the permeability of the component cells is doubled for a temperature rise of 10° to 30° C. Observations with specially constructed thermocouples show that leaves exposed to sunshine are often many degrees warmer than adjacent shaded leaves, and air-currents often lead to fluctuations of several degrees within a minute. Such temperature differences must give rise to alterations in the permeability of the cells. These permeability variations coupled with tensile stresses in the sap will lead to the transport of materials from the more permeable cells.

EDINBURGH.

Royal Society, July 7.—J. H. Ashworth, vice-president, in the chair.—D. H. **Scott**: Fossil plants of the Calamopitys type, from the Carboniferous rocks of Scotland. The stems of four plants are discussed. They are referred, provisionally, to the family Calamopiteæ, a group, placed among the Pteridosperms or "Seed-ferns" on the ground of anatomical characters. *Calamopitys radiata*, from the Cementstone group of Dumbartonshire, has pith that contains elements resembling tracheids, and may therefore have been a "mixed pith." The strands of primary wood surrounding the pith are large. The secondary wood is remarkable for the enormous width of many of the medullary rays, so that the woody zone consists largely of cellular tissue. This feature distinguishes the plant from all the other known species of the

oup. *Endoxylon zonatum* was found in the Carbon-rous Limestone series, Dalry, Ayrshire, by the late r. John Young of Glasgow. The large pith consists nolly of cellular tissue, surrounded by a number of attered strands of primary wood. The secondary ood has very narrow, and usually low medullary ys, and is notable for showing well-marked annual gs, characterised by the narrow-celled zones of autumn-wood." The bark is preserved in this ecimen, an unusual feature. The other specimens ustrate two species of the genus, Bilignea, a genus unded by Dr. Kidston, and characterised by the ct that the pith is wholly replaced by a massive ntral column of short tracheids, presumably for the orage of water. This genus may be described as istophyton with the pith replaced by a column of ater-storing tracheids. Whether this peculiar struc-re was derived from a primitively solid wood or m a pre-existing pith cannot yet be decided.—L. **Ince**: On a class of partial differential equations. quations of which $\frac{\partial^2 z}{\partial x^2}+\frac{\partial^2 z}{\partial y^2}+(n+1-x^2-y^2)z=0$ is pical are considered; a set of particular solutions d a solution of a general character are obtained.—r Thomas **Muir**: The theory of circulants from 1900 1920.

PARIS.

Academy of Sciences, June 23.—M. Guillaume gourdan in the chair.—G. **Bigourdan**: The deter-ination of time, and the modified use of the ethod of corresponding heights. A review of the s methods that have been used, with discussion the relative advantages and disadvantages of ch. The method of corresponding heights of own stars has for a long time been considered the st exact: a modification leading to increased pre-ion is proposed.—F. **Widal**, P. **Abrami**, A. **Weill**, d **Laudat**: Hydremia in the course of diabetes der insulin treatment. Variations in the refractive dex of the serum. Insulin profoundly affects ter metabolism, causing blood dilution, and these anges can be conveniently followed by the refracto-eter.—Pierre **Weiss** and Mlle. Paule **Collet**: Para-gnetism independent of the temperature.—V. **Grignard** and R. **Stratford**: The catalytic decomposi-on of hexahydroaromatic and saturated fatty drocarbons. Contribution to the study of the cking of petrol. The decomposition of pure indivi-ual hydrocarbons has been studied; anhydrous aminium chloride was used as catalyst and the tem-ratures were generally between 120° and 150° C. he gaseous and liquid products of the reaction were entified. The substituted cyclohexanes undergo a uble transformation, a cracking increasing with the gth of the side chain, and isomerisation leading to lymethyl cyclohexanes. Both fatty hydrocarbons d substituted cyclohexanes give normal butane der the action of aluminium chloride.—Jean **Effront**: The toxicity of copper salts.—M. Giovanni attista De Tori was elected correspondant for the ction of botany in succession to the late M. Warming.—Marcel **Légaut**: The systems of points in a plane.—**Maneff**: Gravitation and the principle of action d reaction.—M. de **Fleury**: Concerning the use of ht or extra-light alloys for the pistons of internal mbustion engines.—P. **Dumanois**: Concerning iation motors with very high compression. Some nsequences resulting from the use of an antiknock-g compound, such as lead tetra-ethyl, in petrol used f aviation motors.—V. **Michkovitch** and E. **Mallein**: prism astrolable with an impersonal micrometer.—fred **Lartigue**: The application to thermodynamics the representation of Fresnel.—P. **Lejay**: The use of lamps with several electrodes in electrometry.—Georges **Chaudron** and Hubert **Forestier**: Study of the decomposition of ferrous oxide. Anomalies of expansion corresponding with its instability. It has been shown in an earlier communication that ferrous oxide is unstable below 570° C. and that it decomposes according to the reaction $4FeO \rightleftharpoons Fe_3O_4 + Fe$. The present paper gives the result of a study of the velocities of these two inverse reactions.—P. **Laffitte**: The spectroscopy of explosions. With a gaseous explosive the spectrum of the explosive wave, and that of the period of combustion, is a continuous spectrum, the only lines observed being those of elements in the walls of the containing tube. For a solid explosive, the spectrum is continuous without lines.—A. **Damiens**: The absorption of carbon monoxide by cuprous sulphate in the presence of sulphuric acid. Application to the production of hydrogen from water gas. With cuprous oxide dissolved in strong sulphuric acid, the absorption of carbon monoxide is complete up to the limit one molecule of carbon monoxide to one molecule of copper sulphate, and no gas is evolved by this solution in a vacuum. The carbon monoxide is removed by dilution and warming.—Edmond **Bayle** and René **Fabre**: Study of the fluorescence of the alkaloids of the isoquinoline and tetrahydroisoquinoline groups, papaverine, narcotine, hydrastine, and their products of oxidation.—E. **Darmois** and A. **Honnelaitre**: The electrometric study of the acidity of mixtures of malic acid and molybdic acid. The results of the measurements confirm those obtained by the polarimeter: the latter method, however, is much more sensitive.—P. **Lasareff**: A possible cause of the anomaly of gravity at Koursk (Central Russia).—E. **Chaput**: Two types of alluvial sheets: monogenic and polygenic terraces.—Emile **Saillard**: Estimation of raffinose in sugars. Proportion of raffinose in molasses.—R. **Courrier**: New researches on folliculine. Contribution to the study of the passage of hormones through the placenta.—D. **Bach**: Variations of the concentration of hydrogen ions in the course of the assimilation of the ammonium salts of strong acids by *Aspergillus repens*.—A. **Fernbach** and N. **Schiller**: The rôle of the reaction of the medium in elective fermentation.—G. **Petit**: The morphogemy of the kidney of the sirenians.—Ph. **Joyet-Lavergne**: The evolution of the cytoplasmic elements in the cycle of *Aggregata Eberthi*.—A. **Donatien** and F. **Lestoquard**: Pernicious anæmia of the sheep and the goat.—B. **Issatchenko**: Sulphuretted hydrogen fermentation in the Black Sea. The reduction of sulphates to sulphuretted hydrogen in the Black Sea appears to be due to an organism identical with one described by Beijerinck and by van Delden under the name of *Microspira æstuarii*.—MM. **Ménard** and **Foubert**: The technique of the treatment of medico-surgical affections by ultraviolet light.—H. **Penau** and H. **Simonnet**: Experimental pancreatic diabetes and insulin.

COPENHAGEN.

Royal Danish Academy of Sciences, February 1.—N. E. **Nørlund**: On the series of interpolation. A determination of the class of functions which may be represented by the usual expansions of the interpolation theory.

February 15.—J. L. W. V. **Jensen**: Results of some earlier mathematical investigations, hitherto unpublished: (1) Asymptotic determination of the roots of the Q-function of Prym.

March 14.—N. **Bjerrum**: On the dissociation constant of methyl alcohol, worked out together with Miss Unmack and L. Zechmeister. Methyl alcohol dissociates reversibly into ions, and the dissociation

constant is determined at different temperatures and ion-concentrations.

March 28.—Harald **Bohr**: Quasi-periodic functions. General determination of the classes of functions which can be resolved into arbitrarily chosen vibrations (harmonic or otherwise). The inquiry forms a generalisation of the theory of the usual Fourier series. With the help of certain generalisations of the notion of periodicity, it is possible to reach a simple and complete characterisation of the class of functions indicated.

April 11.—P. O. **Pedersen**: On electric sparks. (2) An experimental investigation on time-lag in the electric spark and on spark-formation under various conditions. (3) It is shown that the present theory of the electric spark in some essential points is contradictory to experience and particularly to the experimental results described in (1) and (2). The outline of a new spark theory is sketched.

April 25.—L. Kolderup **Rosenvinge**: The marine Algæ of Denmark, (3): Ceramiales. The Danish species of this order, contributions to their morphology and development, their fructification and occurrence in Danish waters.—Niels **Nielson**: An equation of Lagrange studied by Cayley. The memoir gives a generalisation of the equation studied by Cayley (*Journal de Crelle*, vol. 53). The parameter 4 is replaced by any power of any prime number whatever. The memoir gives the necessary and sufficient conditions for the solution of this generalised equation, also formulæ which allow certain equations corresponding to parameter 4 to be solved at once or proved insoluble.

ROME.

Royal Academy of the Lincei, May 4.—C. **Segre**: Curvilinear elements having tangent and osculatory plane in common.—A. **Angeli**: Analogies in behaviour between certain derivatives of benzene and the corresponding derivatives of the aliphatic series.—G. **Armellini**: Observations on the diameter of the sun made at the Royal Rome Observatory on the Campidoglio. The meridian observations taken at this observatory during the past forty years are used as the basis of calculations of the sun's diameter. The results are independent of any personal factor and are subject only to a very small error due to the inclination to the vertical of the micrometer wires of the transit instrument. The mean value of the radius of the sun at the mean distance, increased by radiation, is found to be $R = 16'1{\cdot}40'' \pm 0{\cdot}02''$, which is almost coincident with that usually accepted, namely, 16′1·18″.—G. **Gherardelli**: Oblique algebraic curves with only autodual branches.—A. **Myller**: Concurrent directions on a surface emerging from the points of a curve.—M. **Picone**: Necessary and sufficient conditions for the existence and calculation of a periodic solution for the most general system of ordinary differential equations.—G. **Charrier**: Oxidation of 2-*N*-phenyl-$\alpha\beta$-naphthatriazole by means of alkaline potassium permanganate solution.—G. R. **Levi** and G. **Natta**: Action of aluminium sulphide on certain organic compounds. At high temperatures, the action of aluminium sulphide on benzene results in the formation of various condensed aromatic hydrocarbons. Under similar conditions, phenols or naphthols are transformed into the corresponding oxides, whereas from alcohols of the aliphatic series, mercaptans may be obtained in good yield and free from organic sulphides.—B. **Oddo** and D. **Curti**: Oximic and iminic compound of the phthalein of phenol.—A. **Desio**: Geological constitution of certain islands in the Ægean Sea.—A. **Clementi**: Osmotic pressure in terrestrial invertebrates. Just as is the case with the vertebrates, so also with the invertebrates, the osmotic pressure of the internal fluids of the organism is less with terrestrial than with marine species, the maximum value in the case of one and the s organism being less in the internal fluids than in solid tissues.—M. **Sella**: Observations on the deve ment and anatomy of the myotome in the Teleos

Museums and the British Empire.

IT was fitting that the Museums Association should hold its annual conference this year at Wembley, for the Exhibition is a great museum of Empire, a marvellous example of that education by the visual appeal of concrete objects which is the special characteristic of museum teaching. The inspiration it might afford to the large gathering of museum officials from these islands and from the Dominions overseas was well brought out in the presidential address of Dr. Herbert Bolton, of the Bristol Museum. Trained at the Manchester Museum, for many years director of one of our oldest and best provincial museums, personally acquainted with museum work in the Dominions and the United States, and one who has achieved scientific and academic distinction in the course of his professional labours, Dr. Bolton is eminently fitted to take advantage of the situation, and his constructive criticisms are worthy of respectful scrutiny.

That the museum method is of practical use to practical men is shown clearly enough by the British Empire Exhibition, and so successfully that the Prince of Wales has recently advocated the maintenance of the Exhibition throughout another year. What is still more important is that the impulse given should be guided into those permanent institutions which are intended for the same purpose. It would, indeed, be absurd to organise a vast temporary show of the Empire and to close down the galleries and collections of the Imperial Institute ; fortunately we are, as it seems, to be spared that threatened disgrace. But, as Dr. Bolton urged, the Imperial Institute should not stand alone ; existing museums all over the country should carry on the work, leading, it may be, to the establishment of independent commercial museums in the large industrial centres. Australia, ever advancing, has shown the way in the Technological Museum of Sydney ; Japan, seizing on that which is good in Western civilisation, has trade museums, not only at Osaka, but also scattered throughout the country. The most remarkable example doubtless is the Commercial Museum of Philadelphia, "which has done more to stimulate the trade and commerce of that city than all the other agencies put together." Not that Britain is so far behind : the museums of Sheffield, Halifax, and Hull, for example, have formed collections of metal-work, textiles, and shipping respectively, while for an example of the special museum of industry we need only recall that of the Potteries at Hanley.

Let us not, however, restrict our view to commerce. Public health, to take an activity so admirably illustrated by the tropical diseases exhibit in the Government Building at Wembley, is a subject that can and should be advanced by our ordinary museums. We

cannot have forgotten how several of them rose to the occasion presented by the War, and Dr. Bolton reminded us of the valuable work then done at the Natural History Museum by research and exposition. But all this can be, and indeed is, pursued with profit in times of peace. The American Museum of Natural History in New York has even founded a separate health department.

Space forbids us to follow Dr. Bolton through the many fields in which museums can be of service to the community, from the highest ideals of art to the manurial depths of agriculture, but we must applaud the emphasis with which he once more urges that the prosecution of research is no less incumbent on museums than is the exposition of its results. Here, however, if not before, we are brought up against a formidable obstacle. While our museum officials either have, like Dr. Bolton, been raising themselves to the level of university investigators, or have been increasingly drawn from the higher classes of university graduates, while they have, in short, become skilled men of science no less than highly trained curators, their numbers have not kept pace with the growth of their collections or with the increased demands made on them by the public. Dr. Bolton takes as his example the British Museum (Natural History). As an interested onlooker he asserts that :

"The tasks with which each man has to deal are herculean, and can never be mastered by any one man. Every scientific man of note in the whole world interested in the sciences represented there visits it for study and inquiry, whilst general inquiries are legion. Collections pour in; the labours of Sisyphus were mild in comparison with those of the staff of this museum, for his labours never increased, whilst theirs are continuously mounting up. But this does not touch the question of research. These men do carry out research, but only by making the hours of life the hours of labour. I do not hesitate to say that in the interests of the nation and of the Empire the national museums call for a drastic reorganisation, in order that their hidden treasures may become available for an Empire's betterment and a people's welfare."

It is, indeed, deplorable that this can be said, and said with truth, of the central museum of the Empire, a museum that renders willing service to the whole world. Not all of Dr. Bolton's suggestions will be accepted without qualification, but on this at least we shall be agreed : that one of the best ways of helping the museums of Great Britain and of the Dominions would be an expansion of the staff of the Natural History Museum. If Dr. Bolton is, as we think, right in his belief that museums can do much to knit more closely the brotherhood of the British Empire, then there could be no more secure investment for such funds as may accrue from "The Great Advertisement" at Wembley.

Electrothermic Processes of Steel Manufacture.

The Manufacture of Electric Steel. By Frank T. Sisco. Pp. x + 304. (London : McGraw-Hill Publishing Co., Ltd., 1924.) 15*s*.

UP to the present time several books have been written which deal with electric steel-making furnaces from the point of view of their electric, mechanical, and thermal efficiency. Not one of them, however, describes with any completeness the operation of the furnace and the making of a heat of steel. It has been evident for some time that this was greatly needed, for although the men directly connected with the manufacture of special steels are thoroughly conversant with the electric process and its advantages and disadvantages, those in the steel industry outside of this field have had very little opportunity of becoming familiar with it. In the present volume the author has endeavoured, with much success, to fill this need by discussing thoroughly the manufacture of electric steel, starting with the raw materials and ending with the teeming of the ingots. After the heat is poured and the ingots stripped, the furnaceman's duties are ended. If he has delivered a first-class ingot to the rolling mill or the forge, this represents his part of the effort necessary to the manufacture of a satisfactory product.

The electrothermic process of steel manufacture is the infant—a lusty one—of the iron and steel industry. Little more than twenty years ago the manufacture of steel by this process was still in the embryonic stage. To-day about 1200 electric furnaces are operating in America and Europe. The advance during the past ten years has been nothing short of astonishing, production having increased from 52,000 tons in 1910 to 502,000 tons in 1920. The recognised ability of this process to produce high quality alloy and tool steel ingots, and the superiority of the process over others in the manufacture of castings, is responsible for this advance. In view of the existing literature, the author has devoted comparatively little space to the description of the furnaces themselves. Even in the case of the Héroult furnace, which is the largest single producer of electric steel, manufacture and construction of the electrical details are only lightly touched on. In the United States of America, Héroult furnaces up to 30 tons capacity are in regular use, and are of a size comparable with open-hearth furnaces.

The electric furnace is unique in ferro-metallurgical processes in that it will produce a high-grade material in tonnage lots. The author claims that the same quantity of steel, say 30-50 tons, delivered by the open-hearth can be made in an electric furnace of a quality

qual to the best product of the crucible pot. One of he great advantages of the electric process is flexibility nd control. It can be operated with cold charges or ot metal. It can also be used for making pig-iron ynthetically or for refining molten cupola iron. The emperature can be controlled within a few degrees. Deoxidation and reduction can be carried to any lesired point and sulphur and phosphorus eliminated lown to traces. Compared with steel made by the pen-hearth or Bessemer process, electric steel has reater density and is much freer from slag and occluded r absorbed gases. It is stronger, tougher, and more luctile.

The outstanding disadvantage of the process is its ost. The author anticipates that this is destined to ecome a less serious handicap as power resources become more completely developed and economy of urnace operation is more thoroughly understood and ractised. Another disadvantage is that furnaces are ften operated by men unversed in deoxidation and hus a steel is produced which is not so good as it hould be. A more thorough training is required for he furnace operators. Moreover, electric furnaces are requently installed as adjuncts to open-hearth furnaces y companies interested primarily in the production of arge tonnages. The electric furnace occupies a field f its own and may, with the greatest economy and best results, be operated in conjunction with another melting operation, but should never be used as a subsidiary to it. To quote the author: "Washing hot metal in an electric furnace and calling it electric steel has done much to give it a bad name."

The chapter on the chemistry of the basic electric process is one of the best in the whole book. The author discusses fully and fairly both the oxidation and deoxidation periods. After deoxidation is complete and the alloy additions have been made, the hot metal lies in the furnace covered by a very basic slag containing up to 65 per cent. of calcium as oxide with 13 per cent. of calcium carbide. Through the agency of these, iron oxides and manganese oxide are almost wholly eliminated from slag and bath, the addition of ferro-manganese and ferro-silicon completing the elimination. The fusible silicates of iron and manganese formed in small amounts have had time to separate from the steel. Carbon monoxide gas has been eliminated by silicon, leaving in its place silica, of which a very small amount remains dispersed in the metal. Sulphur is present in the form of manganese sulphide to the extent of one part in five thousand. It is practically impossible to get it out of the steel. Gases should be almost entirely absent. Except, therefore, for small amounts of manganese sulphide and still smaller amounts of silica, the steel should be free from non-metallic inclusions. In these respects it is markedly superior to even the best open-hearth steel.

The author devotes some attention to the Austrian practice of melting chrome-nickel steel for aeroplane shapes. The charge is melted and refined with the idea of producing a so-called fibrous structure which, according to Kothny, is necessary to meet the Austrian army specifications. He challenges the practice *toto caelo*, and gives very good reasons for concluding that the fibrous condition formerly considered so beneficial to steel is in reality harmful.

Mr. Sisco, who is an American metallurgist, has written a valuable book, and by his own work in this subject is making an important contribution to placing the manufacture of electrothermic steel on a scientific basis. His style is clear and his language apt, and he emphasises his main points so that he may be thoroughly understood by men who operate furnaces. The book will also be of service to college students and young metallurgists for the clear picture it gives of the essentials of the best accepted practice in both basic and acid processes. H. C. H. C.

Tycho Brahe's Observations.

Tychonis Brahe Dani opera omnia. Edidit I. L. E. Dreyer. Tomus X. Pp. xxvii+434. (Hauniæ: In Libraria Gyldendaliana, 1923.) n.p.

THE Carlsberg Foundation and the president of the Royal Astronomical Society are to be thanked for presenting us with a most interesting, if not very readable book. The tenth volume of the works of Tycho Brahe is the first volume of his observations, and contains his observations down to the year 1585. The editor's prolegomena tell the history of the manuscripts in which these observations were recorded, of successive projects for their publication, and of the imperfect publications which have appeared. The obstacles to publication were not, it would appear, entirely material. We are quite accustomed to observations being made by one astronomer and theoretical deductions by another, and Ludwig Kepler's contention, thirty-six years after Tycho Brahe's death, that his observations should be reserved for the emperor alone and those to whom, as a special favour, he should grant the use of them, is what we should nowadays expect to find only in the case of discoveries of commercial value, not of astronomical observations. It will be noticed that the sole right to draw deductions seems to pass with the MS. observations after the observer's death. Happily, Kepler had been the owner, and these observations provided him with the material for his laws of planetary motion and his Rudolphine Tables.

There are two great MS. collections of Tycho's observations, both made under his own direction and both containing notes in his own hand. One, now preserved at Copenhagen, contains the daily or nightly record; the other, now at Vienna, arranges the observations of each year according to the bodies observed. Neither is quite complete. Dr. Dreyer has, where possible, followed the text of the Copenhagen and the arrangement of the Vienna MSS.

The one previous edition of any degree of fulness was that of Albert Curtz, which appeared in 1657–66, but it is defaced by many grave defects. It was based on what is now the Vienna MS. The numerous subsequent projects were based mainly on the Copenhagen MSS. or on Curtz corrected from those MSS. After an abortive project of the Royal Society in 1707, proposals for a complete edition practically died away, the one exception being Hvass's project to include the observations in a complete edition of Tycho's works in 1778. This was inevitable. The observations had for the most part come to belong to the history of astronomy. They had lost their living value. Pingré used for his "Cométographie" in 1783 a copy which Bartholin had prepared for printing and never printed, and the observations of comets were published in full by Friis in 1867. These observations at least could not be superseded.

The present most scholarly edition is probably to be classed as a work of piety rather than as a contribution to the progress of science. But without investigation it is impossible to say how far back observations are useful. A sign of the editor's extreme pains is that where there has appeared to be an error in the record of observations, he has attempted to discover its cause by means of computations.

The student of Tycho will find mixed with the observations mathematical constructions and discussions of the quantities dependent on the observations. These increase the interest of the book to any one who studies the history of astronomy. It would be useful to have in some later volume a glossary of star-names.

J. K. F.

A New Natural History.

The Animal and its Environment: a Text-Book of the Natural History of Animals. By Dr. L. A. Borradaile. Pp. vii+399+4 plates. (London: Henry Frowde and Hodder and Stoughton, 1923.) 18*s.* net.

EVERY zoologist will grant that animals should be studied in relation to their surroundings. Physiologically, as Huxley said, they are whirlpools in the river; morphologically, they are, in part at least, bundles of adaptations, definitely related to environmental conditions. Embryologically considered, they develop in a particular "nurture," and they may develop differently when the circumstances are altered. Etiologically, they must be considered in relation to environmental stimuli and environmental sifting; isolation is often an environmental affair; the pulse of evolution changes its throbs with the climate. Then there is the behaviour of the creature, so largely concerned with thrust and parry between organism and environment. In certain cases we are most impressed with the grip of the environment on the organism; in other cases, what strikes us is the dominance of the organism over its environment. As Prof. Patrick Geddes has neatly put it, life is a balancing between Organism→function→environment and Environment→function→organism

Ofe
Efo

All zoologists recognise theoretically the inseparability of the animal and its surroundings, but the truism has not always been evident in their books and lectures. Therefore one gives a hearty welcome to Dr. Borradaile's new natural history which definitely considers animals in relation to their environment. It may be regarded as a continuation of Semper's unsurpassed "Natural Conditions of Existence as they affect Animal Life" (1881).

The book begins by envisaging animals in their natural setting. The organism runs the gauntlet of physical influences and animate influences. There are relations between animals and plants, between animals and their kindred, between animals and other species, and between the sexes. It does not seem easy, if desirable, to separate the animate from the non-living environment; yet one feels that, just as with mankind, there is a difference between mutual relations among living creatures and the relation between living creatures and their *milieu*, or, let us say, climate. Anyhow, what we should call the more distinctive environmental note is sounded emphatically in the subsequent chapters dealing with the faunas of the sea, of fresh waters, and of the land. Then follow chapters on the evolution of faunas, migration, and internal parasites. The concluding chapter deals with the influence of surroundings upon the animal organism, a consideration of which lands the author in an unnecessary scepticism as to the organism's power of "real initiative."

Dr. Borradaile gives many familiar facts a new setting, but he has also a wealth of fresh material. All is presented clearly and educatively, with a generous supply of interesting figures. There are four very beautiful coloured plates. The book is to be strongly recommended in itself and as a supplement to other modes of treatment. There are very few words in

t that could be dispensed with, and we do not know hat the author could have used his space to better ffect, but we venture to suggest for a new edition hat more space should be given to the inter-relations etween plants and animals and to the seasonal changes f environment. Dr. Borradaile has deliberately re- rained from discussing theories of evolution (as to he steps and factors in the historic process), but we annot agree with his view that "these subjects are ut remotely connected with that of the relation etween the individual and its surroundings, which s best studied for its own sake." This seems like a eaction to biological statics, quite inconsistent with he temper of a very dynamic book. The existing elations between organisms and their environments nust, of course, be described and analysed, but sooner r later they must also be studied as historically letermined results. And in this inquiry the changes f environment from age to age must be appreciated. Prof. Huntington, thinking chiefly of the climatic factor in man's history, writes on "The Pulse of Asia"; the zoologist cannot afford to lose hold of his clue. There is a pulse in evolution.

In regard to the chapter on parasitism, where the author shrewdly recognises the heterogeneity of the phenomena, we think that he misses an opportunity of striking out from an outworn conventional concept. "Parasitism" is a too convenient label and it has been badly strained; there are (see Borradaile) at the very least half-a-dozen different kinds of parasitism. That seems to us to indicate the one-sidedness of the environmental grouping in general. Just as we have plankton and nekton in the open sea, illustrating one of the great organic dichotomies, so there is a sharp contrast between a tapeworm and a trypanosome. But we are not blaming Dr. Borradaile for the intricacy of Nature; we are rather, in our hyper-criticism, paying our best compliment to a notable new departure in natural histories. We hope it will have the great success it deserves.

Chemistry of Colloids.

Colloid Chemistry: Wisconsin Lectures. By The. Svedberg. (American Chemical Society Monograph Series.) Pp. 265. (New York: The Chemical Catalog Co., Inc., 1924.) 3 dollars.

COLLOIDAL solutions of the suspensoid type, although not always of immediate technical importance, have many advantages as material for the investigation of the quantitative factors in disperse systems. Sols can be prepared with particles of known and regular size, and, provided conditions of formation are carefully regulated, the systems can often be reproduced within quite narrow limits. The stability of these colloidal solutions does not depend to any great extent on the hydration of the particles, and is therefore not affected by the previous treatment of the solution to the same degree as in sols of the emulsoid type. Indeed, the suspensoids approximate most closely to the purely physical conception of a colloidal system as particles of small size dispersed in a pure continuous medium.

The numerous and fundamental researches of Prof. The. Svedberg have mostly been concerned with colloids of this type, and in the present volume, which embodies a course of lectures delivered at the University of Wisconsin in 1923, this work is summarised with copious references to the related discoveries of other investigators. The title "Colloid Chemistry" is thus misleading unless read with some emphasis on the subtitle. For example, only fifteen pages of the whole book are devoted to gels, and emulsions are scarcely mentioned at all. The author apologises for his bias in the preface, but it should have been indicated in the title of the book.

When, however, the restricted scope of the volume is realised, its value becomes greater than it would be if it were a more general treatise. The author is naturally impatient and distrustful of the merely qualitative or at best empirical experiments which are common in colloid chemistry, and so tends to confine his summary to accurate work on well-defined systems. The methods of formation are first considered and include an interesting account of the work of the author on the electrical dispersion process first worked out by Bredig. In this section the usual methods of purifying colloidal solutions are discussed, including several types of apparatus for electro-dialysis developed in the last few years. In the second part the colloidal particle is considered as a molecular kinetic unit, and the determination of Avogadro's number from the rate of sedimentation of these particles, giving values in remarkable agreement with those obtained by other methods, is described in detail. Among the methods by which the size of colloidal particles can be found is mentioned the calculation from the width of the lines in the X-ray diagram, which should prove a serviceable approach to this difficult determination in the future.

In the third section, under the title of "The Colloid Particle as a Micell," such subjects as adsorption, electrophoresis, coagulation and gel formation are introduced. This portion of the book is worked out in much less detail than the first two sections, and the author wisely refrains from dealing with the tangled mass of results which makes up our knowledge of the coagulation of colloids by electrolytes, and confines his remarks to fairly general statements. Peptisation,

again, with the mass of empirical information which represents practically all we know of that phenomenon, is dismissed in a single paragraph; and protection, of such great importance in technical work, is treated in an equally cursory manner.

It is, perhaps, unreasonable to expect a new branch of science to develop evenly in all directions, but in reading this book one is struck by the extent to which investigators in colloid chemistry have been occupied with systems in which water is the continuous medium. The extreme sensitiveness of aqueous suspensoids to slight traces of impurities, and the variation in properties of emulsoids with minute changes in the concentration of hydrogen and other ions, make the most heroic precautions necessary to avoid complete vitiation of results. The detailed study of non-aqueous and in particular of non-ionising liquids as the dispersion medium is now imperative, if only to clear up some of the results obtained with water. Prof. Svedberg's book indicates what can be done with fairly simple systems with specially designed apparatus, but we can look forward to results even more astonishing and important in the near future.

The author must be congratulated on writing so clearly in a language which is not his native tongue, and also on amplifying his narrative with more than a hundred excellent illustrations, most of which are original. The formal diagrams of the apparatus are frequently supplemented by photographs taken in the laboratory. It is a pity that the printing of the mathematical expressions is so amateurish, so that at times, as for example on pp. 94 and 151, the result is more decorative than intelligible. The value of the book to the scientific worker is increased by the selection of key references which is so constant a feature of the author's publications. For those without the time or opportunity to read the papers in the original, the volume provides an excellent summary of important work in the field with which it deals.

P. C. L. THORNE.

Our Bookshelf.

The Peaks, Lochs, and Coasts of the Western Highlands; Penned and Pictured with One Hundred Photographs. By Arthur Gardner. Pp. xi + 169 + 100 plates. (London: H. F. and G. Witherby, 1924.) 15*s.* net.

THE value of this work rests on its collection of photographs, most of which are excellent in quality and well illustrate the structure and character of the Scottish Highlands. The most beautiful are those of the western coast to the south of Skye. Those of the mountains in the interior have a certain monotony which is, however, instructive, as it represents the frequent recurrence of the same physiographic types. The text consists of an account of the author's journeys with hints to other photographers. The information is too indefinite to serve as a guide, and includes little as to the history, natural history, or geology of the country. The author expresses interested ignorance as to the nature of some of the rocks illustrated by his photographs, which might have been easily removed by reference to a geological map. He deplores the extent of the country devoted to deer forests, both on economic grounds and because they render much of it inaccessible during the usual holiday season. He laments the closing of inns which has rendered impracticable to most pedestrians some of the most beautiful routes across the country. The author also regrets the inconsiderateness of the landlords in planting the clumsy Austrian instead of the picturesque Scottish pine, from which it may be inferred that the author is a better photographer than forester. The book, as a useful collection of geographical photographs, will be of most interest to those who wish for a picturesque souvenir of the western Highlands.

The Hampshire Gate. By H. G. Dent. Pp. 179 + 14 plates. (London: Ernest Benn, Ltd., 1924.) 8*s.* 6*d.* net.

OF the southern inlets into England, physical circumstances have made the Solent and Spithead, with the valleys that give access to them, one of the most important. This may be termed the Hampshire Gate. Its value was very marked when Winchester enjoyed the full significance of its site as a focus of routes in southern England. The importance of Southampton dwindled with the Portuguese discovery of the Cape route to India, which involved the diversion of much Mediterranean trade, but eventually it revived with expansion of Empire and the growth of American trade. Miss Dent's book treats of the Itchen basin and is mainly a study in historical geography. The relation between physical conditions and trade routes is clearly shown. A considerable part of the book is naturally devoted to the port of Southampton. Winchester gets relatively little notice. The study, so far as it goes, is a useful piece of work, and is a good example of regional treatment in geography. The maps are small but clear.

History of the Great War, based on Official Documents. Medical Services: General History. Vol. 3: *Medical Services during the Operations on the Western Front in 1916, 1917, and 1918; in Italy; and in Egypt and Palestine.* By Maj.-Gen. Sir W. G. Macpherson. Pp. viii + 556. (London: H.M. Stationery Office, 1924.) 21*s.* net.

THIS volume deals with the medical arrangements of the War in France, Belgium, Italy, Sinai Peninsula, Egypt, Palestine, and the Senussi Expedition. Particularly detailed were the arrangements in the Somme battles of 1916, the advance to the Hindenburg Line (1917), Vimy Ridge (1917), Messines (1917), Ypres (1917), Hill "70" (1917), the German offensive of 1918, the Lys region, and the final advance to victory, ending with the occupation of Mons on November 11, 1918. Apologies are offered that the volume could not be made more attractive to general readers. It is hoped that omissions may be made good by a study of the maps and charts which are in profusion.

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

The Pressure in the Reversing Layer of Stars and Origin of Continuous Radiation from the Sun.

THERE seems to be at present a wide divergence of views regarding the magnitude of pressure in the "reversing layers" of stars. While earlier investigators assigned to it a pressure of one to ten atmospheres, on the basis of pressure shift of lines to the red, these experiments do not appear to carry much weight at present. Fowler and Milne (Monthly Notices R.A.S., vol. 83, p. 415, 1923) actually assign to it a pressure of the order of 10^{-3} to 10^{-4} atmospheres.

The following speculations will show that probably an accurate method of determining the pressure may be developed from the limit of series absorption of elements in the Fraunhofer spectrum. To introduce the subject, let us start with the well-known fact that in the Fraunhofer spectrum of the sun the Balmer series of H absorption lines abruptly terminate at $H\zeta$, while in the flash spectrum no less than 35 Balmer lines are found. Here the ionisation theory does not help us, for all Balmer lines require the same H atom (in the diquantic state) for absorption. We are therefore confronted with the fact that as continuous radiation pours through the H(2) atoms, pulses which lift the electron up to the 8th quantum orbit are freely absorbed, but pulses which would lift the electron to the higher orbits somehow fail to be absorbed in spite of the presence of suitable absorption centres. Something prevents the development of the H-orbits beyond certain limits.

The next step is naturally to identify this agency with the congestion in the reversing layer due to high concentration of particles. In order that the nth-orbit may be developed, the electron should be capable of passing to an average distance of $0{\cdot}532 \times 10^{-8} \times n^2$ cm. from the nucleus. But if within this distance it comes under the influence of a second nucleus, or another electron, there can be no free development of the orbit: the electron will become either free, or attach itself to another nucleus. Hence for rays shorter than $H\zeta$, the H(2) atoms in the particular layers treated will lose their power of picking up the pulses corresponding to the Balmer series, but will exercise a sort of general, though much enfeebled, absorption on all radiation beyond $H\zeta$, somewhat after the manner of X-ray absorption. This part will be freely emitted only by higher layers, where the pressure has fallen to sufficiently low values; in other words, if the solar atmosphere were composed of H(2) atoms only, part of the continuous spectrum beyond $H\zeta$ would originate from somewhat higher levels than the redder part of the spectrum.

The idea helps us to get a clearer view of the origin of continuous radiation from the sun. For what has been said of H(2), absorption is a general phenomenon, and can be extended to all other elements. In fact a scrutiny of the Fraunhofer spectrum shows that quantum orbits higher than the 5th or the 6th (total quantum number) are rarely developed. The following examples illustrate the point :[1]

Element.	Last Series-line in the Fraunhofer Spectrum.	Corresponding Wave Number of final Orbit.
H	H_ϵ, $\nu = N\left\{\frac{1}{2^2} - \frac{1}{7^2}\right\}$	2238
	$H\zeta$, $\nu = N\left\{\frac{1}{2^2} - \frac{1}{8^2}\right\}$	1714
Na	$2p_1 - 6d$, $\lambda = 4668{\cdot}60$	3062
	$2p_1 - 6s$, $\lambda = 4751{\cdot}89$	3437
Mg	$2P - 6D$, $\lambda = 4351{\cdot}94$	3649
Ca	$2P - 4D$, $\lambda = 5188{\cdot}85$	6385
	$2P - 5S$, $\lambda = 4847{\cdot}29$	5028

For every one of these elements conclusions similar to that in the case of hydrogen hold. Thus, since the higher members of the series lines are in the ultra-violet, there will be cumulative continuous absorption on the short wave-length side. Hence, as a rule long waves will come from deeper layers, short waves from higher layers. How satisfactorily this view accounts for the distribution of energy in the solar spectrum will be evident from the following passage: "Both the observed curves of distribution of energy in the solar spectrum (by Wilsing and Abbot) agree in having a much more pronounced peak than the black body curve, in being depressed below the latter in the violet (*the drop of intensity on the violet side of the maximum being very sudden*), and in coinciding with the black body in the extreme infra-red" (Milne, Phil. Trans., A, vol. 223, p. 218).

Thus for different rays we have different photospheres, but the distances separating the extreme photospheres probably do not differ by so much as 100 km. The photospheres and the reversing layers thus get very much mixed up. Owing to the rapid density gradient of luminous matter (except probably in the case of such atoms as are maintained by selective radiation pressure) the luminosity of the concentric layers round the sun decreases very rapidly. For example, it is well known that if, when obtaining the Fraunhofer spectrum, exposures of longer duration than 1/100 sec. are given, there is no contrast, all dark lines becoming bright. But to obtain the spectrum of layers about 100 km. from the disc during total solar eclipses, exposures of 4 to 10 sec. are required. This shows that the so-called dark lines of the Fraunhofer spectrum are intrinsically 100-1000 times more luminous than the bright lines of the flash. Hence when we expose for the Fraunhofer spectrum, the time of exposure is too short for the chromosphere, which does not, therefore, contribute anything to the resulting photograph. In other words, Fraunhofer absorption is caused by layers close to the disc, the higher chromosphere contributing nothing to the process.

These ideas may be extended to stars. According to a rough calculation, if n is the quantum number corresponding to the last absorption line of the Balmer series in a star, $n \propto \left(\frac{T}{P}\right)^{\frac{1}{8}}$. I have been able to collect the data for three A-type stars, α Cygni (ab. mag. $-4{\cdot}5$), α Lyræ (ab. mag. $+0{\cdot}6$), α Canis Majoris (ab. mag. $+0{\cdot}9$). In α Cygni, 24 Balmer lines are developed, in Vega 17 (up to $H\rho$), and in Sirius 13. Now α Cygni is a typical giant star, Sirius is a typical dwarf, and Vega lies between them. It is generally admitted that the pressure in the reversing layer of giants is much lower than in dwarfs, and hence the great development of Balmer lines in α Cygnus can be easily understood. Sirius also shows more Balmer lines than the sun, and this is to be ascribed to the joint action of higher temperature and lower pressure in its atmosphere.

For an exact estimation of the pressure from such

[1] See Russell, *Astrophysical Journal*, vol. 55, p. 130. According to some authors, H_ϵ is the last absorption-line of the Balmer series. It is always difficult to trace the last line, as it is usually very faint.

data we must wait for further theoretical and experimental work. Much of the idea contained in this communication is to be found in papers by Fowler (*Phil. Mag.*, vol. 45, p. 20), Urey (*Astro. Journ.*, Jan. 1924), Wright (NATURE, vol. 109), Becker (*Zs. f. Physik*, vol. 18, p. 335).

MEGH NAD SAHA.

The Indian Institute of Science.

IN the first column of his article on chemical research in India, in NATURE of June 28, Prof. Thorpe makes reference to the past history of the Indian Institute of Science. I held the office of director for the first half of the period since it was created; and I am glad to have an opportunity of relating the facts with regard to the Institute, now that it is "under the new regime."

In the first place, the term "original purpose" requires some explanation. The proposal to establish a "university of research for India," by the late Mr. J. N. Tata, goes back to the opening of Lord Curzon's viceroyalty, when the matter was first brought to the notice of Government. After much discussion between Mr. Tata and the Government of India, matters took a practical turn when, in the cold weather of the year 1899–1900, Sir William Ramsay went out to India, on the invitation and at the expense of Mr. Tata, to advise on a scheme. Sir William advised in favour of establishing an institution with nuclear departments of chemistry, engineering, and applied bacteriology, but suggested that the main work of the organisation should be to develop industries directly, and that projects should be taken up, developed until they arrived at a paying stage, and then handed over to commercial concerns. The Government of India rejected this suggestion as altogether unsound, and I entirely agree with their conclusions.

Professor (now Sir Orme) Masson and Col. Clibborn, principal of Rurki Engineering College, were then asked to report upon Mr. Tata's scheme, and to make recommendations as to carrying it out. They drew up an eminently practical report, recommending the establishment of nuclear departments, a library, etc., much on the lines of Sir William Ramsay's report, but pointing out that the function of the Institute should be restricted to the provision for advanced study and research. The only section of the report with which I am in disagreement is the building proposals, which, as Col. Clibborn afterwards told me, were drawn up rapidly, and were not checked. The report was accepted by the Government of India and by Mr. Tata.

In August 1906 I was offered the appointment of director, being informed by letter by the Secretary of State for India that "in accordance with the will of the late Mr. J. N. Tata" it was proposed to found an institution for advanced study and research, particularly in applied science; and, on accepting the appointment, I was given copies of printed minutes of the Government of India, setting forth the whole story of the Institute, and confirming the idea that the report of Masson and Clibborn had been definitely accepted and must be considered the basis of the organisation which I had to develop.

I did not know until I arrived in India a few months later that Mr. Tata's heirs held a view of the matter different from that which had been communicated to the home Government. They held, in spite of the opinion of the Advocate-General, Bombay, that they were not bound by the will to carry out the scheme agreed upon by Mr. Tata and the Government of India, and they had informed the Government of India that they were only prepared to proceed with a scheme which left in their hands a measure of control far beyond that claimed by Mr. J. N. Tata at any time. In a note on their proposals, Lord Curzon had pointed out that they wished to establish a private institution financed out of the public funds.

Though working compromises were arrived at from time to time, it was not until 1910 that the matter was settled, and then settled on unsatisfactory lines; for to the constitution, as finally adopted, Lord Curzon's criticism might well apply. Further, all agreements prior to Mr. Tata's death were cancelled, and the representatives of Mr. Tata's heirs declared their intention to use every effort to divert part of the funds of the Institute, and the whole of the accumulated balances, which alone were available for properly equipping laboratories, to the establishment of departments dealing with "social and economic studies." Actual and definite proposals for the creation of departments of social and political history, and of certain medical studies, were put forward, and I have masses of documents dealing with these matters. Thanks to the support which I received from the then Resident in Mysore, and to the then Dewan of Mysore, I succeeded in resisting these proposals; but this gave rise to resentment, and before the end of 1909 I well knew that I should have my work cut out to hold on to my post for the eight years of active service in India for which I was appointed.

On the basis of compromise we had begun building operations in May 1908, and a provisional committee was appointed on which the Tata family was represented. The committee did not, however, support the idea of establishing departments of social studies and was wrecked before the end of the year. Since however, small contracts which the committee had entered into were still running, Government requested me to carry on. In the autumn of 1909 a provisional council came into existence. I laid before this body proposals based upon the Masson and Clibborn scheme, which had been agreed to in Mr. J. N. Tata's lifetime. An attempt was made to modify it with the view of including social studies, but the majority was against the proposal. The provisional council then entered into contracts for building, etc., amounting to more than 100,000*l.*, and all appeared to go well. However, the political element were not to be beaten. They found a flaw in the constitution of the council, and in May 1910 I was informed by Government that I must spend no more money until certain legal formalities had been completed.

I believe that I should have been well advised if I had cancelled all contracts, dismissed my office staff, etc., and shut down. Such a course would have been officially correct, but contrary, at least, to civilian tradition in India. It was clear that Government dare not help me. The Bank of Madras did, however, come to the rescue, and I was prepared to risk accepting loans on my own account. I carried on for five months; but I knew that the resolution of thanks passed by the reappointed council was not an unanimous resolution of good-will.

By July 1911 the laboratories, etc., were sufficiently advanced to allow of students being admitted, and the Institute actually opened. For a moment the future looked promising, but not for long, for difficulties arose in which the later failures, now to be corrected by "the new regime," found their origin. In their report, to which I have already referred, Masson and Clibborn pointed out that trouble would undoubtedly result if members of local educational and scientific services were elected to the governing body, as interests were certain to come into conflict. Were the Institute to develop on the lines they (Masson and Clibborn) laid down, and provide facilities for stu-

and research in pure and applied science, it must necessarily come into conflict with the interests of the University of Madras. On the other hand, the departments of industries of Madras and Mysore might find in its staff and laboratories the means of developing their industrial projects. Actually, before I left for home on leave in April 1912, I found that the political opposition had added to itself a service opposition, opposed to carrying out the policy of the Masson and Clibborn report, and supporting the idea of developing the Institute on industrial lines. The position was fairly hopeless, and before leaving for home I laid the whole matter before the Education Department.

During my absence from India an unexpected development took place. In the month of September I received a communication embodying what was said to be a resolution of the council, asking for an explanation on certain matters connected with the building operations, but couched in such language that I could only return to India by the next mail, and proceed directly to Simla, where I asked that a full inquiry into my administration of the Institute should be held with as little delay as possible. I was received most sympathetically, and I was informed that notes on the matter were in my favour, as it was obvious to the authorities that an attack on me had been organised by my staff. I doubted it, but returned to Bangalore to find out. I then learned the following facts. The resolution had been compiled by the official members of the council. It had been read through, or had been said to have been read through, at a council meeting, and passed; but a legal member of the council, on receiving a copy of it, stated in writing that he did not recognise it, and that it prejudged every issue that it raised. I further learned that the officials would oppose an inquiry; and later, when the Viceroy, as our Patron, ordered that an inquiry should be held, and that in the meantime I should return no explanation in answer to the resolution, they flouted his authority, demanding an explanation of me, and when I refused to comply, they addressed a communication to the Education Department recommending that I should be removed from my office without any inquiry being held.

The inquiry was held in May and June of the following year (1913). It was a lengthy business. Every one who had ever been connected with the Institute was asked to come to Bangalore, and to give evidence, but not on oath. I was not asked to be present, and I heard none of the evidence, and yet the terms of reference were "to inquire into the conduct of the director." Towards the end of June I was invited to meet the committee, and to tell the story of the Institute down to the year 1911, but not later. Before the committee broke up I was sent for, and told that it proposed to give me the substance of its report to the Viceroy. What this amounted to was this,—that on two occasions I had failed to circulate papers to the Council, and that I should cultivate better relations with the political element. The matter about the papers had come out in evidence, but I pointed out that the records would show that it was untrue. The second item involved acceptance of the scheme for political studies, which would have brought me into direct conflict with Government. I had been warned to this effect the day I landed in India.

It did not need the assurance of the Indian official who acted as secretary to the committee—I can mention the matter at this distance of time—to make it perfectly clear to me that the attack which the official members of the council had led against me had failed completely; but I knew perfectly well that as a non-official I could not win in this conflict. That the Education Department was in a dilemma was obvious, and contrary to the hopes of my official opponents they made no move until, in the month of September, they wrote me about a further money grant for the completion of certain buildings. It was clear that they wished the matter to be dropped; but a fresh outburst on the part of the official members of the council, who complained that the result of the inquiry had not been issued, resulted in a telegraphic summons to me to go to Simla. When I arrived there I was informed verbally that the situation could only be solved by my resignation, and it was suggested that I should retire on my pension at the end of the following March. The prospect of release was inviting; but on my return to Bangalore a document came into my hands, practically by accident, which put an entirely new complexion on the matter. It was a copy of a printed minute of Government, dealing with the inquiry, and containing all that Government dared say about it, and a great deal more than it dared publish. With reference to myself, it was the finest testimonial I ever received, and if I ever destroy the rest of the vast accumulation of papers relating to this business, I shall keep it as such. However, it showed that, following my resignation, it was proposed to dispense with the services of two members of my staff, who were not, knowingly, the subjects of the inquiry, and a third was to be removed to Madras to avoid competition between his department and a somewhat similar but inferior department in a Madras institution. I at once informed Government that I would not resign upon any terms.

However, my position was an intolerable one, and it was clear that if I stayed on I should have to carry out a policy which I believed to be wrong. Even the stimulus of fighting against it would be lacking. I therefore intimated my willingness to resign, provided that my colleagues were satisfied. Two years' furlough, followed by pension, were actually due to me, and I only asked that the circumstances of my resignation should be made clear in a *communiqué*. This was agreed to, but the *communiqué* was never issued. The late Prof. Rudolf, professor of applied chemistry, agreed to accept six thousand pounds by way of compensation, and he was appointed honorary technical adviser to the Institute, and the other proposed removals were cancelled. Prof. Rudolf left India in March (1914), but I did not get away till the end of June, exactly two years after the passing of the resolution which gave rise to the trouble.

Within a few months an official ex-member of the council was appointed to the vacant post of director. The new day dawned, but the afternoon seems to have clouded up rather badly.

The "new regime" will have found buildings, equipment, and organisation much as I left them at the end of eight somewhat strenuous years, and for which I had to beg most of the money. It will have found a policy against which I fought, losing the battle and also my appointment at the same time. Had I been contented to adopt a policy of *laissez-faire* I should have had an easier time. I might even have earned the commendation of the powers, at the expense of my own self-respect. It now remains for the "new regime" to sweep away the rubbish and carry on from where I left off. If this is done I shall have nothing to regret.

MORRIS W. TRAVERS.

23 Stafford Terrace, Campden Hill, W.,
June 28.

DR. M. W. TRAVERS knows better than any one else the inner history of the events he describes. The report of my committee dealt with conditions as we found them, and the recommendations were made with the sole object of indicating a remedy for the very unsatisfactory industrial condition in which

India now finds herself. No one who has visited Bangalore can have failed to recognise the great pioneering work which Dr. Travers did there; but the fact that he was unable to carry through does not necessarily mean that, under different conditions, possibly determined by past experience, the outcome might not be different. Some Poetic Allusions to Phenomena of Plant Biology.

IT is with a peculiar pleasure that one finds observations, ordinarily recorded in the precise words of scientific usage, appearing in the beautiful and fanciful diction of the poets. The following examples may be familiar to many, but I have not seen them mentioned elsewhere in this connexion.

It has been shown by A. R. C. Haas that the soluble pigments in many flowers act as indicators, and give a measure of the hydrogen ion concentration of the sap, which in some flowers becomes less as the petals age and wither. This colour change has been noted by Edmund Spenser, and in recent times by A. E. as follows:

Astrophel.

Transformed them, there lying on the field
Into one floure that is both red and blew;
It first grows red, and then to blew doth fade,
Like Astrophel, which thereinto was made.

The Great Breath.

Its edges foamed with amethyst and rose,
Withers once more the old blue flower of day:
There where the ether like a diamond glows
Its petals fade away.

The first is the imagery of mythology, the second uses the same illustration to contrast the brief life of a flower with the unending procession of days.

Again Tennyson gives us a description of the yew tree in stanza 2 of "In Memoriam," which contains these lines:

O not for thee the glow, the bloom,
Who changest not in any gale,
Nor branding summer suns avail
To touch thy thousand years of gloom.

Beyond this stanza the early edition makes no further detailed reference to the yew. Later editions, however, provide one additional stanza, a new thirty-ninth being intercalated.

Old warder of these buried bones,
And answering now my random stroke
With fruitful cloud and living smoke,
Dark yew, that graspest at the stones

And dippest toward the dreamless head,
To thee too comes the golden hour
When flower is feeling after flower;
But Sorrow—fixt upon the dead,

And darkening the dark graves of men,—
What whisper'd from her lying lips?
Thy gloom is kindled at the tips,
And passes into gloom again.

Here Tennyson guards against the too literal interpretation of "who changest not in any gale," and gives a wonderful description of the liberation of the pollen and its result of many months later, the formation of the red berry, red as a glowing tip on a piece of wood kindled by fire. The berry falls, the glow is quenched, and gloom follows. This natural sequence of pollen and berry, coupled with the use of the word "kindled," so suggestive of a fiery hue, makes it seem impossible that Tennyson can have intended to allude to the lighter green of the young leaves—an explanation which, I believe, has been put forward.

To A. E. again we are indebted for the description of the recovery of turgor in plants wilted by the heat of day, which is contained in "A Summer Night":

The falling of innumerable dew,
Lifts with grey fingers all the leaves that lay
Burned in the heat of the consuming day.

We have all seen the "grey fingers," but it takes a poet to stamp the picture in an untarnishable phrase.

Finally, in "Prometheus Unbound," Shelley alludes to the liberation of oxygen in photosynthesis, imagining that the spirits "Which make such delicate music in the woods" dwell in bubbles, thus:

The bubbles, which the enchantment of the sun
Sucks from the pale faint water-flowers that pave
The oozy bottom of clear lakes and pools,
Are the pavilions where such dwell and float
Under the green and golden atmosphere
Which noon-tide kindles thro' the woven leaves;
And when these burst, and the thin fiery air, . . .

Have we as yet got so very far beyond "the enchantment of the sun" as an explanation?

Electrical Properties of Thin Films.

THE mechanical properties of thin films on the surface of water have been the subject of many investigations; yet little is known of their electrical properties. Whilst the electrical properties of those films which are formed on the surface of soluble capillary active substances can be readily investigated using a method elaborated by Kenrick (*Zeitschr. f. physik. Chem.*, xix. 625), no method, so far as I know has yet been described which can be applied to

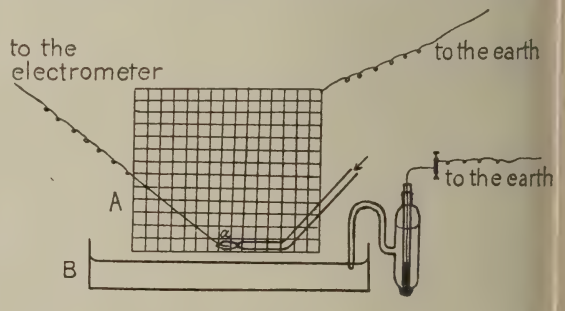

FIG. 1.

films formed by insoluble substances. The following simple arrangement has been designed which has given quite satisfactory results in this case.

A thin platinum wire *a* was heated to white-heat by a minute gas flame in an earthed Faraday cage *A* hung over the surface of water in the vessel *B* (Fig. 1). The platinum wire was connected with a quadrant electrometer, and the water in the vessel with the earth through a decinormal calomel electrode. Between the earth and the electrode, a variable electromotive force could be inserted. The experiments have shown that the potential of the wire follows closely the variations of the potential of the water surface when the distance between the platinum wire and the water surface does not exceed 7-8 mm.

If we put now a droplet of oil on the water surface the electrometer shows instantly a change of the potential of the wire. In order to compensate this

change a definite electromotive force has to be inserted between the calomel electrode and the earth. In this way it can easily be shown that a monomolecular layer of oleic acid makes the water surface more positive by 0·22 volt, whereas the same effect for lauric acid amounts to 0·27 volt and for olive oil to 0·33 volt. On replacing the water in the vessel by a solution of a capillary active substance, data are obtained which can be compared with those given by the Kenrick method. In this way I have found a positive effect equal to 0·27 volt for 50 per cent. acetic acid and a negative one equal to 0·38 volt for a molar solution of chloral hydrate, whereas the Kenrick method gave for the same solutions in a fair agreement +0·285 and −0·365 volt respectively (*Zeitschr. f. physik. Chem.*, in press).

The experiments are to be continued, and a detailed account will be published in the *Zeitschr. f. physik. Chem.*

The Oogenesis of Lithobius.

MISS S. D. KING in her note on the oogenesis of Lithobius published in NATURE of July 12, p. 52, says:

"Yolk formation is from nucleolar extrusion, of which two phases can be distinguished; first, an early extrusion of particles budded off from the large central nucleolus, which retains its individuality, and, secondly, an extrusion of particles derived from the fragmentation of this nucleolus."

In a paper on the oogenesis of Lithobius now in the press (Proceedings Cambridge Philosophical Society), I have shown that there is no fragmentation of the nucleolus. It can be seen in the most highly developed oocytes obtainable from the ovary as a completely acidophil structure with prominent vacuoles. The nucleus at this stage lies just below the chorion. As to budding of the nucleolus, there are two kinds of nucleolar extrusions: small circular bodies, which generally form the secondary nucleoli, and large irregular bodies, which are first plastered round the nuclear membrane, where they may bud off smaller pieces, and are later detached and lie in the cytoplasm.

Nor is there any direct evidence for the statement that "the later extrusions enlarge after proliferation to form the definitive yolk spheres." All that can be said with certainty is that the nucleolar extrusions precede yolk formation, although a few may exist side by side with yolk spheres.

With regard to the Golgi apparatus, I have definitely established that during fragmentation it undergoes fatty degeneration, and gives rise to fatty yolk, which forms the uppermost area in the centrifuged egg, whereas the true vitelline yolk is thrown down. Both direct and indirect evidence has been adduced in favour of this statement. The fatty yolk is intensely blackened by chrome-osmium alone; with Da Fano it turns brownish. The mitochondria, the nucleus, and a few unchanged Golgi elements form the central area of the centrifuged egg.

In view of the remarkable transformation of the Golgi elements in the oocytes of Lithobius, which is paralleled only in Saccocirrus (Gatenby), and also in view of the egg-like giant spermatocytes of Lithobius, it was considered desirable to extend the investigations to the Golgi apparatus in the male germ cells. No fatty degeneration of the apparatus takes place in these cells. In the spermatogonia the apparatus consists of at least one circular element, in the centre of which is a definite archoplasm. During the remarkable growth phase the circular element proliferates profusely, so that the spermatocytes are full of such elements. Each circular element may also divide in such a manner as to form two very regular crescents, each with an archoplasm. During meiosis the distribution of the Golgi elements is quite haphazard. During spermateleosis all the mitochondria and the majority of the Golgi elements form the tail sheath, but a few Golgi elements are plastered round the anterior face of the nucleus, and probably give rise to the acrosome.

Zoological Laboratory,
Cambridge, July 14.

Approximate Rectification of the Parabola.

RECENTLY I had to ascertain with some precision the length of the curved path of a shot in air at elevations up to 40° as compared with the horizontal range.

The material available was a quantity of trajectories worked out in full detail by "small arcs." The error in summing these small arcs and considering the result to be the length of the curved path was within ±0·10 per cent. The greatest heights were also contained in the calculations.

Assuming the parabola of equal angle of projection and of equal height as standard and comparing the actual length, the length of a similar circular arc and the "fudge" formula $L = R \sec E$ to this standard, the result is surprising, and is as follows in parts *per thousand*:

Elevation in Degrees.	10	20	30	35	40
Parabolic error	0	0	0	0	0
Actual length	+1·0	+4·5	+7·0	+ 8·5	+ 8·5
R sec E . .	0	0	0	+ 0·8	+ 4·5
Circular arc .	0	+2·0	+10·0	+18·0	+31·0

On comparing notes with professional ballisticians, I cannot find that the "fudge" R sec E was known to Tartaglia, Galileo, Newton, or Benjamin Robins, nor has it yet been found in any modern book on ballistics or geometry. I hit on it myself by pure chance. Can any reader of NATURE supply a reference?

Electric Charges by Friction.

THE following quotations from a book printed nearly one hundred years ago (Murray's "Elements of Chemistry." Sixth edition, Edinburgh, 1828) bear on the observations of an anomaly in frictional electricity referred to recently in NATURE (June 21, p. 914). "A white silk ribbon rubbed against a black one becomes positively electrified; but if the black ribbon be worn so that the colour is faded, and if the white ribbon be heated, the latter will be found to be negative, and the black positive."

As a result of consideration of a large number of such experiments, M. Coulomb inferred "that where the particles suffered a transient compression, they would be more disposed to become positive; where they suffered dilatation, the tendency would be to the reverse state."

This inference seems to receive support in the recent experiments with rough and smooth ebonite rods.

The Radioactivity of the Rocks.[1]

By Prof. JOHN JOLY, D.Sc., F.R.S.

THE subject of the radioactivity of the rocks is one whch offers to the geologist considerations of the first importance respecting the history of the surface features of the globe. To the chemist it offers considerations even more fundamental in character, for it appears to throw a certain amount of light on the past history of the chemical elements during geological ages—knowledge attainable in no other way at the present time.

The fact that the radioactive elements of the uranium family are widely, indeed universally, distributed in the rocks was determined, in the first instance, by the present Lord Rayleigh, who in 1906 published an extensive research on rocks of various kinds. Later it was found that elements of the thorium family are just as widely distributed; and further, it was found that there appears to be a certain well-sustained relation between the amounts of these elements present in igneous rocks when the uranium and the thorium content of the same chemical division of the rocks are compared.

Lord Rayleigh in his earliest paper came to the conclusion that the acid rocks contained more radium than the basic rocks. This result has been confirmed by subsequent work. He found that the mean content of the igneous rocks was considerably greater than that of the sediments. This result, which has also been confirmed, throws light on the high radioactivity of the more slowly collecting oceanic deposits—the red clay and the radiolarian ooze. Similar results have been arrived at for the thorium content of rocks.

I have already referred to the fairly constant ratio which exists in the quantities of uranium and thorium in igneous rocks. When we estimate the uranium from the radium, using the equilibrium factor $3{\cdot}4 \times 10^{-7}$, we find in basalts about $0{\cdot}44 \times 10^{-5}$ gm. of uranium and $0{\cdot}9 \times 10^{-5}$ gm. of thorium. In intermediate rocks the corresponding ratio is 0·76 : 1·64. In the acid rocks (granites) the ratio is 0·8 : 2·0. For acid intrusives it is 1·1 : 2·3. The mean of all acid rocks affords 0·9 : 2·0. In short, we find a ratio which does not vary much from 1 : 2. In individual rock specimens this ratio is often seen to hold; but exceptions are found. It is best revealed in the general means, as, under the conditions, might be expected. To what may this fairly constant ratio be ascribed?

The rate of decay of uranium is nearly three times as fast as that of thorium. Obviously the precise numerical value of the ratio referred to must have been changing throughout geological time and must continue to change. The uranium will have dwindled to insensible amounts long before the thorium. But the fact that there appears to be a numerical ratio which is preserved through the chemical divisions of the rocks, although the actual amounts involved may differ largely, must be significant of some controlling condition.

Now if all rock families derive their origin from some world-magma by certain processes of differentiation which do not select between the parent radioactive substances, uranium and thorium, then we can account for the observed constancy of ratio. For if granites, for example, take from the parent magma a certain quantity of both the parent radioactive elements without disturbing their primal ratio, and if diorites and syenites take a different quantity, but still without disturbing the original ratio, then in subsequent ages the ratio of uranium to thorium, varying in the same manner both in granites, diorites, syenites, and the mother magma, will continue to be alike in all.

This subject naturally leads us to the interesting conclusion reached by Lord Rayleigh that the first formed silicate in rocks—zircon—is most exceptionally rich in radium. We seem to know little about mineral genesis in rocks. Hence we find here a tempting field for speculation. The oxide of zirconium is isomorphous with the oxides of uranium and thorium. It seems probable that herein is some explanation of the accretion by zircon of radioactive elements from the magma. The radioactive centre thus originating becomes the centre of a minute field of intense ionisation. These conditions may be supposed to be favourable to the crystalline growth of molecules around it. The radioactive nuclei are small and their field of influence is restricted, but the surrounding chaos is trembling on the verge of equilibrium and there is unlimited time. Of the chemical effects of radioactivity Soddy says: "The great chemical reactivity of otherwise inert substances in presence of the radioactive materials must always be remembered in the interpretation of their action." In fact it has been supposed by workers on this subject that there is first a dissociation of molecular aggregates and temporary formation of free atoms under the influence of the radiations, rendering the substance highly reactive, as in the nascent state. Much experimental evidence for this statement might be quoted. In some such way the growth of mica or hornblende around zircons may originate.

This concentration of radioactive elements gives rise to the radioactive haloes found in certain rock-forming minerals of early consolidation—notably the brown micas. These very beautiful manifestations of radioactivity in the rocks raise many questions. It is remarkable that the earlier observers regarded these minute objects as organic in origin. The only basis for this view appears to have been their behaviour when the containing mineral was heated to a high temperature. The halo then vanished or lost all definition.

Far-fetched as such an explanation may appear, we must remember that the real history of these objects was at that period absolutely undecipherable. It required a generation of scientific discovery and the brilliant advances which brought to light radioactivity, the transforming atom, and the phenomena of material radiation, before the real explanation was possible. Sollas, before the period of these discoveries, suggested that they were in some way caused by the presence of rare elements in the nuclear zircon which is in most cases to be found in the halo. To go any nearer to the truth was then impossible. The

[1] Hugo Müller lecture (slightly abridged), delivered before the Chemical Society on February 28.

wonderful similarity of dimensions and structure revealed by these objects seems to have escaped notice.

With the advent of radioactivity the explanation is simple. In this new domain, which borders at once upon radioactivity, chemistry, petrology, and geology, many curious facts have come to light. For the first time we can determine by direct visual observation the presence of radioactive elements in the rocks, and, given the halo, a single measurement of its radius tells us at once whether it was generated by uranium or by thorium. Some haloes there are which are generated in a curious way from the passage of the gaseous emanation of the uranium family which has wandered from the radium whence it originated and has become occluded in certain nuclei. These then have become centres of development of haloes possessing characteristic dimensions telling of their exotic origin. These are the only three sorts of haloes reconcilable with the known sources of radioactivity.

It is desirable to recall here the foundations upon which our knowledge of haloes is built. The fundamental assumption is that the α-ray is the all-sufficient source of the halo. For example, the atomic *débâcle* from uranium to lead takes place in fifteen stages. Of these, eight are attended by the expulsion of a helium atom as an α-ray carrying a charge of two units of positive electricity. The range in air of these rays varies from 2·7 cm. (in the case of the ray from uranium-1) to 6·97 cm. (in the case of radium-C_1). If the atomic disintegration occurs within a mica flake, these ranges are reduced some two thousand times.

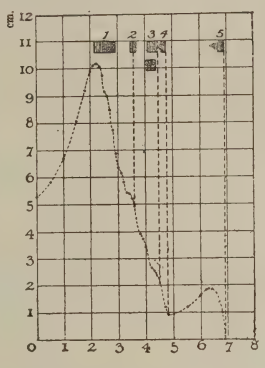

FIG. 1.—Ionisation curve for uranium haloes.

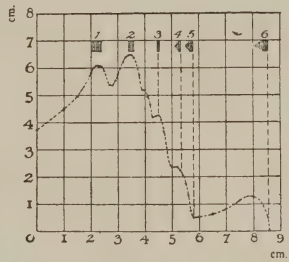

FIG. 2.—Ionisation curve for thorium haloes.

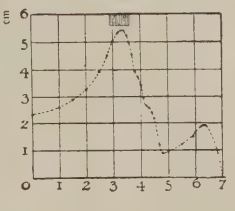

FIG. 3.—Ionisation curve for emanation haloes.

We know something about what happens along the track of the ray in gases. The particles of the gas are ionised. Bragg plotted the curve of ionisation. He found that the curve was alike in form for α-rays of long range and of short range, and that the ionisation rapidly increased just before the ray lost so much of its kinetic energy as to be no longer effective. The range of the ray is measured to the point where—effectively—it comes to rest.

Suppose now that in the brown micas the ionisation is attended with certain chemical changes—for example, affecting the iron present—so that the mica is darkened in colour. Then this darkening intensifies along the path of the ray and is darkest just at the approaching end of its trajectory. If uranium is contained in a minute particle—a crystal of zircon most generally—the eight rays will all act upon the surrounding mica within a certain spherical volume which has the zircon at its centre and the outermost boundary of which is defined by the path of the helium atom discharged from radium-C_1, the most penetrating of the rays. The radius of the uranium halo will therefore be about the two-thousandth part of 6·97 cm.—or, say, 0·035 mm. In the case of an emanation halo the outer dimension will be the same, for the penetrating ray of radium-C_1 decides its boundary, but the effects of the four least penetrating rays of the uranium family will be absent. If thorium be in the nucleus, then seven rays operate on the mica and the outer dimension is determined by the range of thorium-C_1, which is 8·62 cm. in air and becomes 0·041 mm. in biotite. Uranium and thorium haloes are thus readily distinguishable.

To determine the inner features, we lay out the ionisation curves of the eight rays of the uranium family, or the seven rays of the thorium family, or the four rays which generate the emanation halo and add the ordinates at sufficiently close distances. This gives us the integral curves of ionisation, and these curves we find bear close comparison with the actual halo. The apices of the curves correspond to the rings of darkened mica which lie around the nucleus. The depressions of the integral curve are depicted in the mica as annular areas of feeble darkening. But here a difficulty arises. Our method of arriving at these curves assumes that the rays affect the mica as if they travelled in parallel lines. But in fact they diverge, and when we plot the integral curve so as to allow for this divergence, we get a curve not at all accordant with the halo.

In order to explain why the halo does not exhibit the effects of the divergence of the rays, we may assume that something like photographic reversal or solarisation occurs when one ray traverses the path followed by a preceding ray. This weakens the density of the inner parts more than it affects the outer parts of the halo, and it follows that the ultimate effect is much the same as if the rays had been parallel. This view also explains the early appearance of the outermost ring of all; for a minimum of reversal affects this. It is not at all an improbable assumption that reversal plays an important part in the generation of the halo as we see it.

We see, then, that we can foretell the appearance and dimensions of the inner parts of a halo according as it originates from uranium, thorium, or radium emanation. If we find haloes not in accordance with these dimensions, we must conclude that we are dealing with new radioactive elements, unless some means of reconcilement be forthcoming. Herein we find an important application of the radioactivity of the rocks to the advance of chemical science.

When we look at the integral curves of uranium, thorium, and emanation haloes, we see that in the case of uranium and emanation (Figs. 1, 2, and 3) a single conspicuous crest occurs which must appear in

the halo as an inner ring of small radius. In the case of thorium, two such crests appear close together. Those early rings are the first appearance we find. Their measurement will tell us what elements we are dealing with, although the halo is only in an incipient stage of development. Such rings are found well developed and easily measurable around nuclei of extreme minuteness.

We possess in haloes a means of identifying the presence of radioactive substances in rocks which much transcends in sensitiveness any other known method. The electroscope transcends in sensitiveness chemical gravimetric methods of detection many thousands of times. The billionth of a gram of radium per gram of rock may be detected by the electroscope. But we may have a zircon nucleus of the five-thousandth of a millimetre in diameter. We may suppose it endowed with a radium richness twenty-five times as great as obtained in the richest zircons measured by Lord Rayleigh. Then the mass of radium involved is only 3×10^{-18} gm. or the millionth of the billionth of a gram. Such nuclei may show a perfectly measurable and identifiable ring.

The reason for this extraordinary sensitivity is obvious. The halo is always old—often very old, and through all the successive ages of geological time the ionisation effect is slowly adding up. It is, in fact, not found in the younger rocks. We perceive the final effects of such feeble radiation exactly as we may detect on the photographic plate, after long exposure, stars which are for ever invisible to the eye.

On this account, also, the halo is important to chemical science. It gives us a means of exploration, almost uncanny, into the past history of the chemical elements. By its help we may answer questions which may not be approached in any other way. We can tell if the known radioactive elements formerly differed in their mode of disintegration or if other radioactive elements existed in the remote past. The important question as to whether during geological time radioactivity has been a diminishing phenomenon may be answered by the halo. For the halo is, in fact, a sort of hieroglyphic, a writing in the rocks, which admits of interpretation based on to-day's experience of what radioactivity involves. All this is equally important to the geologist. For he wants to know, as vital to the past history of the surface changes of the earth, whether the known radioactive elements evolved thermal energy as they do to-day, or whether in the past notably more or notably less energy from this source affected the earth.

That halo-reversal is an actual and definite phenomenon seems certain. We cannot, indeed, be sure that it is quite similar in character to photographic reversal; but it acts much in the same manner and there is considerable probability that the two phenomena are very much the same in character.

The theory of photographic reversal may be stated in a few words. The action of light on the photographic plate is photo-electric in nature. Electrons are released from the silver halide each bearing a certain quantum of energy derived from the absorbed luminous vibratory energy. These electrons penetrate a certain distance from the illuminated point, which remains positively electrified, and create around it a negative electrostatic field. This ionised system constitutes the latent image. It may persist for months or years. If we apply a developer, the energy, potential in the latent image, is expended in promoting chemical interaction between the ionised silver halide and the developer. In this process the silver is liberated and is built up in the ionised region to form the visible image. Such is the typical course of events in the case of normal exposure.

Suppose, however, we prolong the exposure or use a very powerful source of illumination. The electrostatic field around the illuminated point grows stronger and stronger until finally the insulation breaks down. There is then re-combination of positive and negative ions and the plate is restored to its original state. At this stage development gives no visible image. The image has, in fact, been reversed, the former latent image having disappeared. This is the first

FIG. 4.—Uranium haloes in various stages of development. ×76. From Leinster Granite (Devonian).

reversal. If exposure be continued beyond the point of reversal, the original phenomena are repeated and a new latent image is formed like the first one, and so with continuous exposure the events in the film are repeated. The successive reversals may be demonstrated by exposing for increasing periods consecutive areas of a photographic plate.

The α-ray carries a certain quantum of energy according to its initial velocity when it leaves the transforming atom. The ray consists of a helium atom carrying two unit positive charges. In its passage through the mica it does work of ionisation. The original chemical bonding is disturbed, and under the influence of the ionisation, atomic systems are built up which are stable just as the latent image is stable. But it is conceivable that a second ray traversing the same or a nearly adjacent region may destroy this equilibrium and cause a reversion to the original equilibrium or to some new state of atomic equilibrium. The former case would result in the restoration of the original state of the mica: the latter may involve a new chemical bonding. As a matter of observation the new bonding appears, at least in some cases, to result in bleaching of the mica. Possibly successive "images" and reversals may occur. In experiments

on the age of haloes, Rutherford produced very intense coloration in biotite by exposing it to strong α-ray radiation. It might be possible to obtain some definite knowledge as to what actually happens by continuing such intense α-radiation for long intervals of time.

In the oldest rocks we certainly find plentiful evidence of bleaching around radioactive nuclei. If these particles happen to be sufficiently isolated, we get a

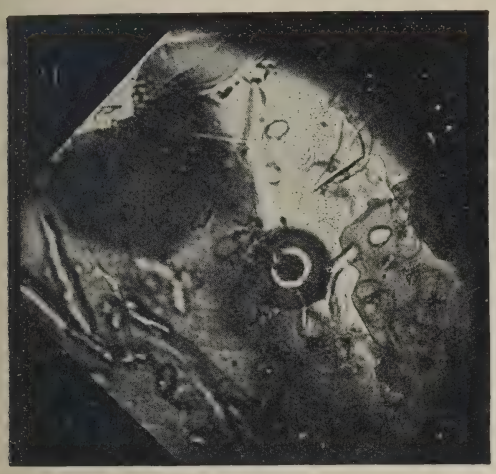

Fig. 5.—X-halo. ×256. Radius = 0·0294 mm. Ytterby mica. (Archæan.)

halo which may show some of its circular bands not as darkened areas but as colourless areas. If the particles are arranged in line and are sufficiently close together we get a bleached band, in the axis of which the particles are distributed. Outside the bleached band we see the effect of normal exposure in the darkening of the mica. Sometimes we find a halo very beautifully reversed or bleached where normally there would be successive dark rings.

In the study of haloes we have to bear other conditions in mind besides these changes brought about by reversal. Side by side in the oldest mica, embryonic haloes and "over-exposed" haloes are to be found, the former merely as a delicate ring of small radius surrounding a very minute nucleus, and the latter as a disc sometimes of almost impenetrable blackness (Fig. 4). Why is this? The answer is simple. The stage of development attained depends on two conditions: the age of the rock and the radioactive richness of the nucleus. These conditions correspond to duration of exposure and strength of illumination in the case of photography. Another obvious fact must also be borne in mind. The halo presented to us in the flake of mica may be a section off the centre of the halosphere, for serial sections of haloes in mica demonstrate that they are spherical. Rock sections revealing haloes contained in sections crossing the cleavage support this conclusion.

The phenomena attending bleaching have also to be held in view when studying these radiographs in very ancient rocks; for it may happen that certain outer or inner features may be obliterated thereby. In drawing the conclusion that a halo cannot be reconciled with known varieties, further evidence than the external dimensions of a few examples is required.

In the micas of Ytterby, which are of mid-Archæan age (pre-Huronian), I have found haloes which cannot be reconciled with haloes originating from known radioactive elements. These haloes I have called X-haloes (Fig. 5). There appear to be two varieties. I distinguish them as X_1- and X_2-haloes. They are fairly numerous. Sometimes, while free from any sign of bleaching, they look pale and washed-out. This is due possibly to some effect of over-exposure, just as an over-exposed plate lacks strength. Or, possibly, it is due to the remarkable metamorphic effects which this mica has generally experienced. In places such faded haloes may crowd together so as to overlap. They vary somewhat in dimensions, both externally and internally. But this effect may be due merely to different stages of development. Generally they consist of a central dark disc surrounded by two or three consecutive wide bands, the innermost one of which may be reversed. I do not think it is possible to ascribe X-haloes to thorium. Moreover, the thorium haloes which occur in this mica are always easily identifiable.

Here, then, is an example of the peculiar use we may make of these radiographs. If my conclusions are correct, we here find evidence either for an unknown element which has radioactively vanished off the earth, or for an undiscovered radioactive element.

In this same mica of Ytterby—but of extreme rarity—certain haloes of minute dimensions and all completely reversed or bleached also occur. I have called these "hibernium" haloes (Fig. 6). The majority are very uniform in dimensions, the radius being 0·0052 mm. A larger size—less abundant—seems present. These are closely 0·0086 mm. in radius. Now the earliest inner ring of a thorium halo is 0·011

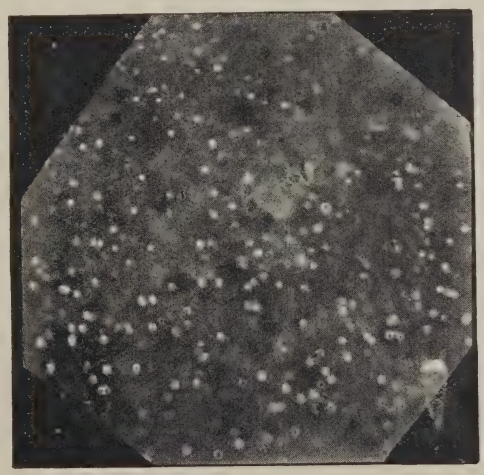

Fig. 6.—"Hibernium" haloes. Radii, 0·0052 mm. and 0·0086 mm. ×106·4. Ytterby mica. (Archæan.)

and of a uranium halo 0·014. If the conversion factor in this mica be taken as roughly 2000, the range in air of the rays responsible for the smaller hibernium halo would be a little more than 1 cm.

Each of these minute halospheres contains a nucleus accurately centred. If two such nuclei are sufficiently adjacent, the resulting halo is of the form of intersecting spheres. Three adjacent nuclei may give rise to a pear-shaped halo. There seems no doubt that their development is controlled by the nucleus in every case. As the bleaching is no objection to their radioactive origin, but in fact supports it, I see no alternative to the view that they are true haloes but of remarkably small dimensions. A prolonged search for other swarms of these haloes has proved unavailing.

It is of interest to notice that these haloes may be—not impossibly—generated by one of the known elements, for they must originate from a substance so feebly radioactive that no known method of observation would detect its radioactivity. This follows from the extremely small trajectory of the responsible α-rays. It will be remembered that Rutherford long ago pointed out that there existed a connexion between the initial velocity with which an α-ray was expelled and the period of the element giving rise to it. Geiger and Nuttall showed that a definite relation was deducible, most simply shown by plotting the logarithm of the constant of transformation against the logarithm of the range of the α-particle. Thus treated, the elements of each radioactive family are distributed approximately along a specific right line, and the lines for the uranium, thorium, and actinium series are sensibly parallel. From this investigation Geiger inferred that elements emitting α-particles of very small ranges would possess so slow a rate of transformation that no known instrumental method would reveal the fact that they were radioactive.

The age-long integration effected in the halo, however, can reveal radioactive phenomena far beyond the power of instrumental measurement. It is, therefore, not impossible that in these haloes we detect the radioactivity of some of those rare elements which this mica first revealed to science.

Lastly, one conspicuous fact is everywhere forced upon us in our studies of haloes—the scarcity of visible radioactivity in the rocks and the immense antiquity of that which we observe. In the absence of this mode of tracing radioactivity into the past, we might quite reasonably have argued that in former geological times many of the known elements were in process of radioactive genesis. The study of haloes rules out this view. Again, what radioactivity we are acquainted with has not originated in recent times. It dates back into the oldest rocks. The appearances which I have endeavoured to describe show this clearly. The reversed or blackened-up haloes of the Archæan are entirely different in appearance from those of Lower Palæozoic age. Indeed the geologist may by these appearances derive strong evidence as to the relative antiquity of the rocks he deals with. We arise from halo-study more than ever impressed with the immense age of the elements, and yet we know that some of them are to-day perishing off the earth and that a definite period is placed to their existence. What the halo ultimately shows is the remoteness of those past ages which probably witnessed the evolution of the elements.

The Malarial Treatment of General Paralysis.

FOR many years it has been realised that the intercurrence of an acute specific fever, such as erysipelas, in cases of general paralysis of the insane, is frequently followed by marked improvement in the general condition, and attempts have been made to procure remissions by the induction of an artificial pyrexia. In 1917, von Jauregg introduced the method of inoculation with malaria. About 5 c.c. of blood are taken from the vein of a patient suffering from benign tertian malaria and immediately injected subcutaneously, intravenously, or intramuscularly into the general paralytic. The average incubation period is about ten days, after which typical malarial attacks appear. When the patient has passed through ten or twelve attacks, the malaria is arrested by the administration of quinine and a course of neosalvarsan is given. Improvement is observed soon after the cure of the malaria, and in early cases of general paralysis the patient may become as capable as before the onset of the disease. Von Jauregg obtained prolonged remissions in more than fifty per cent. of his cases, the most noticeable features being the cessation of fits, better articulation, and general improvement in the mental and physical conditions. Other European observers have reported equally good results; in a series of 296 cases, Gerstmann found remissions in sixty-eight per cent.; Weigandt obtained improvement in forty-four out of fifty patients. In Great Britain the number of patients hitherto treated is small; Worster-Drought found improvement in all except one of twelve early cases; in a series of asylum patients, in whom the disease would be more advanced, improvement has been reported in six out of nine cases.

In dealing with syphilis of the central nervous system, the cerebro-spinal fluid affords an indicator of the inflammatory changes taking place in the brain and spinal cord, and the efficiency of treatment may be estimated by the resultant alterations in the fluid. So long as a positive Wassermann or any other abnormal reaction is given by the fluid, it cannot be considered that the disease has been eradicated. In cases of general paralysis, treatment by drugs has very little influence on these reactions; neither has it been found that inoculation with malaria, although producing remissions, has any effect in diminishing the intensity of the Wassermann and colloidal gold reactions. No patients have been observed for sufficient length of time to determine what period of improvement may be anticipated, but it must be remembered that spontaneous remissions are common during the course of general paralysis, and that relapses invariably follow. In view of the persistence in the cerebro-spinal fluid of the evidence of active syphilis, it cannot be expected that remissions following malarial inoculation will differ from those which arise spontaneously.

In our present state of knowledge, only speculation is possible concerning the mode of action of artificial pyrexia. Drugs, and probably specific antibodies, penetrate with great difficulty into the central nervous system; it may be that pyrexia with leucocytosis in some way increases the accessibility of the actual nervous tissue to the passage of substances from the blood-stream. Purves-Stewart suggests that the remissions are due to the destruction in the febrile reaction of some of the toxins affecting the cerebral cells, the specific organism of the disease being unaffected. He has published descriptions of two cases of general paralysis treated by malarial inoculation, followed by a course of intra-cisternal injections of salvarsanised serum. In the resulting remissions the cerebro-spinal fluid became completely normal in one case, and the pleocytosis was markedly diminished in the other. This result is of great importance in indicating that malarial inoculation, combined with a specific anti-syphilitic treatment which can reach the cerebral cortex, may prove to be a means of completely arresting the disease.

Inoculation with malaria is not entirely without drawbacks; there is a definite risk of the parasite being conveyed to other persons by the mosquito; the Board of Control has issued a letter to asylum superintendents recommending a number of precautions to be adopted against this risk. In advanced cases the attack of malaria may hasten the fatal termination, but, in view of the hopeless prognosis of general paralysis, this mortality cannot be considered as a contra-indication to a treatment which in early cases produces such marked remissions. The serious nature of the disease, and the complete failure of anti-syphilitic treatment to have any effect on its course, demand that every endeavour should be made to investigate and perfect a method which offers some hope of improvement.

Obituary.

Sir William A. Herdman, F.R.S.

THE sudden death of Sir William Abbot Herdman on July 21 will be deeply regretted by naturalists in many parts of the world. For several years his general health had been bad. His only son, George, was killed in the battle of the Somme, and this calamity accentuated an illness from rheumatism which left him partially crippled and with serious heart weakness. He had begun to shake off the rheumatism when his wife died after two days' illness from pneumonia, and since then his health continued to be bad. He had gone to London on the day that he died to be present at the wedding of his daughter, and had arranged to leave Liverpool three days later for the British Association Meeting at Toronto.

Herdman was born at Edinburgh in 1858, and was educated at the High School and University in that city. He graduated in science in 1879, and was for a short time assistant to Sir Wyville Thomson. Then he went to the *Challenger* office, where he worked under Sir John Murray, and began the description of the Tunicate collections, a work which he finished at Liverpool. He went to the latter city in 1881, when the University College was established, as the Derby professor of natural history. In 1919 he retired from his chair (then that of zoology), and became professor of oceanography, a post which he held for a year, when he retired as Emeritus Professor. His connexion with the University of Liverpool did not, however, cease in 1921: he was a member of council and of various committees, and during the Lent term of 1924 he was acting vice-chancellor in the absence, on sick leave, of Dr. Adami. He had a room in the Department of Zoology, and he was there almost daily. At the time of his death he was engaged in a research on the morphology of Ramulina.

During the latter part of his life Herdman was a comparatively wealthy man, and (with his wife) was a generous donor to the University. He endowed the chair of geology in 1916, and that of oceanography in 1919. In 1923 he gave the University a sum of 20,000*l.* to assist in the building of a new department of geology. He endowed an exhibition, and he bought and furnished a building at Port Erin as an institute and club for fishermen. For the last dozen years of his life he had become greatly attached to Port Erin, where he owned a house at which he resided during a considerable part of each year. His interest in Manx affairs was strong, and he was practically responsible for the foundation of the new Government Museum at Douglas.

Herdman's life-work was, of course, marine biology: that he began by a series of dredging expeditions in the Firth of Forth; developed in the *Challenger* office, and continued when he went to Liverpool. There he found a small group of amateur naturalists whom he organised as the Liverpool Marine Biology Committee; he outlived nearly all these original workers. They prosecuted active, systematic, biological investigations in the Irish Sea region, at first hiring steam tugs for their dredging and trawling expeditions. Then they fitted out a biological station at Puffin Island, in Anglesey, and later built two stations at Port Erin, in the Isle of Man. In 1892 Herdman organised the scientific work of the Lancashire Sea Fisheries Committee, and persuaded the latter body to found the Fisheries Laboratories at the University of Liverpool, and at Piel in Barrow. The result of these activities has been a very satisfactory biological survey of the Irish Sea, summarised in five volumes of a "Fauna and Flora," and a long series of papers on fishery subjects written by Herdman and his colleagues, and published by the Fisheries Committee. This work was, at first, financed locally, but, later, it was supported by government grants with results that have not been satisfactory. The local contributions have tended to decrease; there has been an unnecessary control over expenditure, and an insecurity of tenure of post for the scientific men employed.

In 1901–2 Herdman went to Ceylon for the greater part of a year, at the request of the Colonial Office, to study the pearl-oyster fisheries. He went out again

a year or two later at the request of the syndicate of pearl fishers, which had in the meantime leased the fishery rights from the Government. The results of these expeditions was a very complete biological survey of the pearl banks, published in five volumes by the Royal Society, and an hypothesis of pearl formation which has given rise to much controversy. He was, in 1892, elected a fellow of the Royal Society, and was its foreign secretary in 1916–20. He was president of the Linnean Society in 1904, president of Section D of the British Association in 1895, and president of the Association at the Cardiff meeting in 1920. During the war years he was chairman of the Grain Pests (War) Committee of the Royal Society. He was a member of various official commissions and advisory committees, and gave expert testimony before other similar bodies. He received many honours during his lifetime: he was a D.Sc. and LL.D. of the University of Edinburgh, and a D.Sc. of the Universities of Harvard, Durham, Sydney, and West Australia. He was made a C.B.E. in 1920, and was knighted in 1922.

Herdman was, above all, a field naturalist and systematist of the type which seems now to be passing away. His knowledge of species of animals was extraordinarily good: helpful (and at times embarrassing) to his colleagues and assistants. This fine zoological knowledge was of immense value to him in his fishery investigations. He was adventurous, very active, and inclined to "rough it" until middle age: he and his friend Isaac Thompson for a time went regularly to Port Erin Bay to swim during the Christmas vacations. He was a keen traveller and yachtsman, and had visited most countries in the world. For many years he owned small steam vessels which he worked himself up the west coast of Scotland, round St. Kilda, and through the Orkneys and Shetlands on his trawling and plankton expeditions. He always had strong interest in archæological investigation, and with his friend P. C. Kermode did a good deal of excavation in the Isle of Man, while at one time or another he had visited most of the places of anthropological interest in the continent of Europe. In his own home he was at his best: an accomplished talker, most hospitable and good-humoured. On his fiftieth birthday his family presented him with a pipe, and after that he became an inveterate smoker. While his interests were thus very wide, he was first and last a marine biologist, both as an investigator and an expositor, and it is in this direction that his influence was most widely manifested, and will be most sadly missed.

J. J.

MR. EDWIN THOMPSON, who was one of the local honorary secretaries for the Liverpool meeting of the British Association last year, sends the following tribute:

Sir William Herdman was known throughout the world as a great oceanographer. There are thousands who, in addition, knew him as a delightful personality, and there are others who had the privilege of knowing him as the kindest, most cheery, most breezy and sympathetic of men. To have known Sir William Herdman personally was an education in the highest sense of the word; he knew and could teach others how to work and how to play, but he never knew what it was to waste time. The short memoir he wrote about his son, George, who was killed in the War, was, I think, an inspiration to every boy who read it, and I always wished that it had been made public, and I feel that Sir William Herdman's life, if it is ever written, will be an inspiration to every man whether he be interested in science or not.

When Sir William Herdman took a holiday it was to work, and I have had the pleasure of seeing him at sea working with the late Sir John Murray, Haeckel, and others, and also years ago have seen him organise children's parties with an understanding with which one does not usually credit great men of science; he might, in fact, have been the author of "Peter Pan." No man was ever made to feel a fool by Herdman, and it is only a great man who has that attribute. It needs a man with a big brain to lecture on scientific subjects to a large audience in such a manner that the subject is clear to every one, even the least intelligent. Sir William Herdman had this power in an extraordinary degree.

His last years were full of sorrow, but with his characteristic pluck he never let others see the sadness in his heart. The strain had told upon him, however, and he knew every time he went upstairs that he might not reach the top alive, but he did not let that interfere with his work or the pleasure he gave to others.

He died suddenly as he would have wished, without a long illness, which to him would have been a terrible trial. His friends, Liverpool, and the whole world have lost a great man, and those who knew him intimately can to a small extent realise the sadness felt by his three daughters and their pride in having such a father. I would just like to tell how he died, as there were many garbled reports, which gave rise to misunderstandings. He travelled to London on Monday, July 21, and gave a little family dinner on the eve of his daughter's wedding. Before going to bed he went out for a short stroll, as was a very frequent custom of his, and in the street he had a heart attack. Fortunately, a woman was passing at the time, and seeing him in distress helped him into the nearest house, which was a small hotel; but by the time the doctor had arrived he was dead. The doctor then sent for the police, who identified him by papers in his pockets. It is tragic that his family were not with him; but it is far more tragic that the false reports should have caused any misunderstanding or been misinterpreted by those who did not know him.

WE regret to announce the following deaths:

Miss K. A. Burke, assistant lecturer in chemistry at University College, London.

Prof. Heinrich Precht, who was closely associated with the German potash industry and contributed many important investigations in this field, aged seventy-two.

Prof. James Seth, professor of moral philosophy in the University of Edinburgh from 1898 until a few weeks ago, on July 24, at sixty-four years of age.

Current Topics and Events.

RECENT criticism of the British Museum Bill fully justifies the comments in our issue for July 5. Sir Hercules Read, as an ex-officer and former trustee of the Museum, in a letter to the *Times* of July 26, emphasises the point that the objects in the national collection are not duplicates, and that the temporary removal of any specimens other than those of trifling interest would disorganise the exhibition and study series, and would add to the difficulties of the serious investigator. The Trustees, who did not ask for this Bill, would in most cases escape from a difficult or delicate position by exercising their discretionary veto. On the other hand, the provincial museums object to the Bill on two grounds: the categories of permissible loans are not those which they particularly desire, and the conditions imposed are onerous if not impossible. The Museums Association has therefore passed a resolution of protest, and has once more called for a Royal Commission to inquire into the whole question of the national organisation of museums. The resolution, which has been sent to the Prime Minister, is as follows: "This Association regrets that the British Museums Bill No. 2, promoted in the interests of provincial museums, should have been introduced without consulting the body which represents those museums and knows their needs, and expresses a hope that the Prime Minister will be so good as to receive a deputation from the Museums Association, which would explain the urgent necessity for the appointment of a Royal Commission to inquire into the work of all the museums of this country."

THE continued closing of the Museum of Practical Geology, London, was discussed at the meeting of the Museums Association last week, and a resolution upon the subject was passed, to be forwarded to the President of the Board of Education. A question asked in the House of Commons on Monday by Major Church, secretary of the National Union of Scientific Workers, elicited some interesting information on the matter. The question was: "To ask the First Commissioner of Works if he can state how long the Geological Museum will be closed for repairs, in view of the importance of the museum to the nation; and will he state why the structural alterations and repairs now being undertaken were not commenced before." In reply, Mr. Jowett, First Commissioner of Works, said: "It has now been decided to proceed with the erection of a new building at South Kensington to house the offices of the Geological Survey and the Museum of Practical Geology, and a Supplementary Estimate for the provision of funds for this purpose is being presented to the House at an early date. The repairs required to the present building to enable it to be reopened to the public are not being proceeded with, but the administrative work of the Geological Survey will still be carried on, and the public will have access to the Library and Map Room. As regards the last part of the question, the execution of the structural alterations and repairs was suspended pending a decision as to the future of the Museum."

THE annual meeting of the Imperial Cancer Research Fund was held on July 23, when the twenty-second annual report was presented and adopted. The report discloses satisfactory steady progress. The finances are sound, though half the annual income comes from subscriptions and donations. The new laboratory at Mill Hill, adjoining the farm of the Medical Research Council and due to the beneficence of the executors of the late A. C. Stroud, has been erected, and the laboratories at Queen Square continue to make the sound contributions to our knowledge of the biology of cancer which has always characterised their activities. After prolonged discussion the Fund has found a means of co-operating with the British Empire Cancer Campaign through the appointment by the Royal Society and Medical Research Council of an advisory committee which will advise the Campaign on the allocation of funds for investigation. The Middlesex Hospital, the Cancer Hospital, and the Fund have also nominated representatives on the grand council of the Campaign. It is hoped that by this arrangement the newest organisation for the investigation of cancer may have the advantage of the experience gained through many years by the older bodies.

ACTIVITY in the experimental investigation of cancer has recently centred largely around the relation between certain forms of long-continued skin irritation—notably by tar—and the development of malignant tumours. One of the most noteworthy contributions to the same topic, but from the observational side, is contributed by Dr. Alexander Scott, of Broxburn, who has practised for many years among the operatives in the Scottish shale oil works, to the eighth scientific report of the Imperial Cancer Research Fund. We have here a singularly exhaustive study of the inflammatory conditions of the skin brought about by the repeated irritation of crude paraffins and the conditions under which cancer develops in the affected areas of skin. Dr. Scott's observations, which are illustrated by a large number of illustrative photographs, are particularly valuable, because they comprise the history of nearly twenty-five years—a continuity much needed and so often lacking in clinical studies. They bring out clearly the close parallelism between paraffin cancer in man and experimental tar cancer in mice, especially in respect of the length of the prodromal stages and the course of the disease after tumour growth has started. As a result of his work, preventive measures have been installed in the industry: fresh cancers will no doubt develop for some time, as they do in mice, as the result of past irritation, but in the end his pictures will—or ought to—become a unique historical record of something which no longer exists.

"EDUCATIONAL HARMONICS" is the phrase in which the *Times* sums up the character of the debate in the House of Commons on July 22 on the education estimates. With one or two exceptions, the speakers made no attempts to use the debate as an opportunity

for scoring points for their respective parties. There was general agreement that the problem of adolescent education is of paramount importance, and Mr. Fisher and Mr. Wood were to that extent at one with Mr. Trevelyan in his proposal that for the next few years extraordinary efforts should be made, whatever political party may be in power, to provide for a great increase in the number of secondary school pupils. Mr. Trevelyan suggested that their number, which is already double what it was only a few years ago, should be again doubled within the next ten years. He is less sanguine than Mr. Fisher as to the potentialities of day continuation schools, and laid less stress than Mr. Wood on the importance of central schools, but is willing to support local efforts to develop either. There was no discussion of educational aims, and no revival of the proposal made two years ago for a commission of inquiry into the subject; yet, as Mr. Wood remarked, the mere expenditure of much money will never be enough unless the system be right, and unless we know where we are going and what we want to get out of it. Mr. Trevelyan's assumption that "there could be no difference in the main objective in education of succeeding governments" may be convenient for preserving harmony in parliamentary debates, but there is little else in its favour. An authoritative statement on the subject commanding general respect would do more to promote real efficiency than the expenditure of many millions, and is doubly desirable in view of the anticipated great expansion of secondary education.

MR. HOOVER, the Secretary of Commerce, U.S.A., in addressing the Izaak Walton League at Chicago in April last, spoke of the attitude that a good government ought to observe in its consideration of fishery problems. Thousands of generations of free fishermen have established their tradition to catch unlimited fish, but now this tradition encounters the spirit of modern industry. There is over-fishing and depletion, so that already the systematised fishing trade, with the "demonic assistance of the tin can," is rapidly destroying the Pacific salmon rivers. Long ago, villages situated on rivers and seashores established a right to deposit their waste products on the nearest stream or foreshore. Little harm was done originally, but now the modern factory, the great city with its sewerage system and the new oil-driven vessel, are rapidly making tidal rivers and shores incredibly foul, so that another ancient privilege has become incompatible with a fishing industry that seeks to develop as others have done. Finally, the conflict between federal government and local autonomy (as represented by the American States, or the provincial systems of regulation in Great Britain) has, so far, led to confusion of policy and waste of effort. To these problems, Mr. Hoover asks the fishery administrators to bring the contemplative mind, the faith and optimism, and the patience and reserve that come to the followers of Izaak Walton; and, one may add, without any suspicion of cynicism, he asks in vain, for the qualities he postulates do not seem to come to those who look at fishery questions through official windows.

THE leading part taken by Messrs. Chance Bros. and Co., Ltd., in the development of optical glass manufacture and their successful efforts during the War to meet the enormously increased demands are well known. These, however, form only a small part of this firm's contribution to the development of glass manufacture during the last hundred years. In 1824 Robert Lucas Chance purchased the works of the British Crown-Glass Company at Smethwick, and thus provided the nucleus round which the modern works of Messrs. Chance have grown. Ever since then, the name of Chance has been intimately associated with the history of glass making in Britain. The firm's first achievement of outstanding importance was the introduction into England, in 1832, of the manufacture of sheet glass. This was soon followed by the production of rolled plate and later of "figured rolled" glass. In 1840 the firm inaugurated the manufacture of thin glass for microscope cover-glasses, which greatly extended the possibilities of accurate microscope work. For many years Messrs. Chance have provided a large proportion of the world's supply of glass for spectacles, while recent developments include the production of heat-resisting glasses for illuminating ware and of chemical resistance glass for laboratory ware. An interesting record of the firm's activities and achievements is contained in an illustrated pamphlet, "100 Years of British Glass Making, 1824–1924," which has recently been issued by the firm to commemorate its centenary celebrations.

THE building of the Literary and Scientific Institution of Bath was opened in January 1825. During the past hundred years much good work, especially in geology, has proceeded from Bath, as the names of William Smith, Lonsdale, Charles Moore, and H. H. Winwood bear witness; and the museum of the Institution houses many specimens of scientific importance, notably the fossils of the Charles Moore collection. Unfortunately the good people of Bath did not keep up their interest in the side of life represented by the Institution, and of late years, particularly during the War, the building was falling into decay, not without danger to its contents. Now there seems to be an intellectual and material revival. Repairs and rearrangements have been effected by the zeal and generosity of a few, and in one year 9000 visitors have passed through the pillared entrance. But more needs to be done if the Institution is to have a home worthy of its traditions and of its beautiful city. It is proposed to celebrate the centenary next January, and the most appropriate form of celebration will be a pecuniary contribution forwarded to the Secretary, Mr. P. E. Martineau. We cordially commend the appeal to our readers, who will be the more ready to help those who are helping themselves.

THE fourth Annual Report of the Forestry Commissioners for the year ending September 30, 1923, shows steady progress in afforestation. During the year, 10,463 acres were planted with about 18,000,000 trees, mostly conifers, the species used being Scots and Corsican pines, Norway and Sitka spruces, European

nd Japanese larches, and Douglas fir. The cost of planting averaged 7*l.* per acre; and this figure included preparation of the ground, draining, fencing, ctual planting, filling in blanks, and weeding. Except or seed, tools, and wire, the whole of this expenditure was on wages. The total land acquired during the our years amounts to 179,207 acres, of which 121,015 cres are classified as plantable, the remainder being ither too poor or too good for timber production. n addition, eighteen Crown woods, formerly under the Commissioners of Woods and totalling 120,000 acres, vere transferred in 1923 by Act of Parliament to the Forestry Commissioners. Two maps in the Report how the situation of all the areas now under the control of the latter. There are now two schools for he training of woodmen, one at Parkend in the Forest of Dean, and the other at Beaufort in Inverness-shire. Research and experimental work has made good progress. As many as 143 experimental plots, which are regularly thinned and measured, have been established in different parts of England and Scotland. A census of British woodlands is in course of preparation, and a summary of the completed statistics for twelve counties is given in the Report. The Forestry Commissioners were represented at the British Empire Forestry Conference, which was held in Canada during the summer of 1923; and a full account of the important resolutions passed by the Conference is appended to the Report.

"METEOROLOGY in Education" is the title of the reprint, now published, of the papers read on January 3 last at a conference of the Royal Meteorological Society, the Geographical Association, and the Science Masters' Association (Messrs. George Philip and Son, Ltd. 6*d.* net). Sir Napier Shaw, who presided, introduced the subject as the study of weather as a scientific subject, and Mr. J. Fairgrieve in the course of the discussion claimed that the conference was a successful attempt to get geography teachers and meteorologists to talk to each other. Mr. G. M. B. Dobson contributed a paper detailing recent results of research especially in regard to cyclonic and monsoon rains. Mr. L. B. Cundall in a paper dealing with school work in meteorology pleaded for the creation of a joint advisory committee of the three bodies to decide what should be taught in this connexion, and Mr. W. G. W. Mitchell directed attention to the use of wireless in relation to the compilation in schools of synoptic weather charts. During the discussion Sir Richard Gregory and Mr. W. E. Whitehouse both emphasised the position of the teacher of geography, for whom the results of meteorological science were merely initial data for use in the class-room. Dr. G. C. Simpson advised teachers to teach meteorology because it is a body of knowledge to which the pupil should be introduced. In any event the conference made quite clear that the current geographical teaching concerning rainfall distribution in relation to winds and pressure variation requires considerable emendation. Sir Napier Shaw stated that the wind distribution was only known for about three-fifths of the earth's surface.

THE library of the Chemical Society will be closed for stock-taking on August 4-August 16 inclusive, and will close each evening at 5 o'clock from August 18 until September 13.

DR. R. E. M. WHEELER, Keeper of the Department of Archæology in the National Museum of Wales and lecturer in archæology in the University College of South Wales and Monmouthshire at Cardiff, has been appointed Director of the National Museum of Wales, in succession to Dr. W. E. Hoyle, who has resigned owing to ill-health.

IN agreement with the programme of the International Commission for the Upper Air, the Meteorological Office of the Air Ministry sent up twelve registering balloons between March 3 and 22. The *Meteorological Magazine* for July states that of these, nine instruments have been found and returned. Eight ascents were made from the aerodrome at Shotwick, near Chester, and four from Kew Observatory, the losses being respectively 2 and 1. The greatest height reached was 19·3 km., 12 miles, the drifts being towards points between north-north-east and south-east. During five months working, 80 per cent. of the balloons sent up have been found and returned.

A DANISH ship, the *Godthaab*, started from Thorshavn at the end of June, according to the *Meteorological Magazine* for July, to visit settlements in north-east Greenland. The vessel is to keep in communication with Jan Mayen by wireless telegraphy, and meteorological reports are being transmitted via Tromsoe. Reports from the *Godthaab* in the area off north-east Greenland in about latitude 75° N. have been received by the Forecast Division of the Meteorological Office, and they extend the information of the daily weather charts into the region of the Arctic north of the island of Jan Mayen and south-west of Spitsbergen, from both of which places daily reports are regularly received.

UNDER the auspices of the Royal Society for the Protection of Birds, a bird sanctuary has been established near Farnham, in Surrey, consisting of some twenty-seven acres of wild gorse, heather, and woodland, and well watered. This is eventually to become the property of the Royal Society for the Protection of Birds, so that it may be obtained in perpetuity as a wild nature reserve. A watcher who is well versed in wood-craft and bird-lore has been appointed, and an earnest appeal is made for the sum of 500*l.* to provide him with a cottage so that he can continually be on the estate. Donations will be gladly received by the hon. sec., R.S.P.B., 82 Victoria Street, London, S.W., or by Mrs. Minchin, Gorsedene, Farnham, Surrey.

THE marine biological laboratory at Wood's Hole in Massachusetts, founded in 1888 and for many years a centre of attraction to biologists of all parts of America, is to be developed on a great scale by means of a gift of 1,400,000 dollars from the Rockefeller Foundation, the Carnegie Corporation, and a fund endowed by Mr. C. R. Crane of Chicago. A combined laboratory and library building is to be

constructed at once at a cost of 600,000 dollars. At Wood's Hole, which has been called the summer capitol of American biology, zoologists, physiologists, embryologists and botanists gather every summer both for independent research and for theoretical and practical instruction courses. During 1923, seventy universities and research organisations contributed to the support of the laboratory.

By virtue of the Importation of Plumage (No. 2) Order, 1922, and (No. 1) Order, 1923, respectively, the names of the golden pheasant and of the *common or mute swan* were added to the Schedule to the Importation of Plumage Prohibition Act, 1921, which contains the names of certain birds whose plumage may be imported without licence. The Advisory Committee appointed under the Act has now recommended that the common or mute swan should be removed from the Schedule, but that the golden pheasant should remain thereon. The Board of Trade accordingly desires it to be known that an Order will be made in due course removing the name of the *common or mute swan* from the Schedule, with effect from October 1, 1924. On and after that date, the plumage of this bird will accordingly be prohibited from being imported except under Board of Trade licence issued in accordance with the provisions of the Act. The right to import the plumage of the golden pheasant without licence will continue as heretofore.

Dr. N. H. Darton, geologist, has left Washington to join the National Geographic Society's expedition, which is exploring an ancient temple in the Valley of Mexico, the oldest ruins so far discovered in the Americas. Dr. Darton will study especially the sequence of geological events, including the lava flows and the recession of Lake Texcoco, with the view of determining more nearly the exact period of the civilisation which flourished on the American continent some 7000 years ago. Mr. Byron Cummings, the head of the expedition, has already reported remarkable finds among the lava-encased temple mound—finds ranging from pottery, images, and sculpture to parts of human skeletons. It is believed the mound was built on or near the shore of Lake Texcoco originally, but the water line of the lake is now twelve miles distant. The lake had receded a considerable distance when a sudden volcanic eruption half buried the temple mound, which still was inhabited.

A conference on Illuminating Engineering has been arranged to take place at the British Empire Exhibition on Tuesday, August 12 (2.30-5.30 p.m.). The conference is timely in view of the two important conferences just held in Geneva, namely the first International Conference on Industrial Hygiene, and the meeting of the International Illumination Commission. In both cases important papers dealing with illumination were read, and special attention was devoted to the lighting of schools and factories. A report on the proceedings at these two congresses is to be presented, and other papers dealing with public lighting and other subjects will be read. It is also interesting to note that the opportunity will be taken at this conference to discuss the question of the lighting of exhibitions. Fuller particulars of the conference will be obtainable in due course from the hon. secretary of the Illuminating Engineering Society (Mr. L. Gaster, 32 Victoria Street, London, S.W.1).

Our Astronomical Column.

Spiral and Structureless Nebulæ.—The *Observatory* for July contains a letter on this subject by Prof. C. D. Perrine. He criticises Prof. Lindemann's suggestion that the spirals are dust-clouds shining by reflection from the galaxy; he notes in opposition to this view that the Coal Sack and other very dark regions appear to be dust-clouds absorbing the light of the stars behind them; we should therefore expect them to shine by reflection much more brightly than the spirals since they are presumably much closer to the galactic stars; nevertheless they appear quite non-luminous both to the eye and photographic plate while the Andromeda nebula is very luminous. Further, he dwells on differences in the spectra of different spirals, some showing bright lines, others not; these would be difficult to understand if all of them shone by reflected galactic light.

Prof. Perrine considers that the structureless nebulæ are related to the spirals, being at an earlier stage of condensation, with less rapid rotation; both alike are supposed to consist of "cosmical matter." Possibly a considerable part of this may attain incandescence through collisions or electrical excitation, sufficient gas being evolved to account for the absorption spectra.

The variety of opinion that prevails about the nature of the spirals is evidence of the difficulty of the problems that they present. It is well to consider all reasonable suggestions, but not to expect a definite or final solution in the near future.

The Planet Uranus.—Mr. W. F. Denning writes that Uranus will be favourably visible during the ensuing few months. The planet will rise on August 1 at 9 h. 6 m. p.m. and on August 31 at 7·6 p.m. G.M.T. It will be in opposition to the sun on September 12 and will be perceptible during the whole night. Its position is in the southern portion of Pisces, and its present motion is retrograde amongst the small stars in that region. The planet's place may be found from an ephemeris and by the help of a catalogue of small stars. The intending observer should make a diagram containing the places of Uranus and of the stars in the same locality and then examine the sky with a suitable telescope and low power. In this way the planet may be easily identified; but should this method fail, the object may be known by its disc, which will be apparent with very moderate power and will contrast strongly with stellar images in the same field of view. The planet is distinctly visible to the unaided eye, being about 5½ magnitude, and Mr. Denning considers, from many observations made at Bristol, that it might quite possibly have been discovered without telescopic aid, as it has been watched on many clear evenings near opposition in past years and changes distinctly noticed in its position. Uranus and the Moon will make some near approaches during ensuing months:

Research Items.

Witchcraft in Medieval India.—Mr. W. Ivanow directs attention in the Journal of the Asiatic Society of Bengal, vol. xix., New Series, No. 3, to a "witch case" which affords a remarkably close parallel in its details to the practices of European witches. Hamid b. Fadli'l-lah Jamāli (a Sufi of Northern India) records about A.D. 1530, in a collection of stories of miraculous deeds, that when Shaykhu'l-Islām Farīdu'd-Dīn Mas'ud (d. A.D. 1265) was suffering from a serious indisposition, it was revealed to his son in a dream that he had been bewitched, but that the spell could be removed by the repetition of certain incantations over the tomb of a sorcerer, the father of the man responsible for the Shaykh's illness. These instructions were followed, and in the course of repeating the incantations the son of the Shaykh accidentally discovered, hidden in the grave, a figure made of flour into which some needles were stuck, and on which were knotted hairs from a horse's tail. The figure was taken to the Shaykh, who ordered the needles to be drawn out, and the hairs to be unknotted. As this was done the pain diminished, and when all the needles had been withdrawn and all the hairs untied, it disappeared. The sorcerer was apprehended, but—and here the parallel with Europe ceases—was pardoned.

Racial Intrusions in Ancient Egypt.—Sir Flinders Petrie in *Ancient Egypt* for June discusses the origin of the XIIth Dynasty in the light of the results obtained by the British School of Archæology in the excavations at Qau. Up to last season, it was known that there had been a Syrian occupation of Northern Egypt, a Libyan occupation of Middle Egypt, and, there was strong presumption, a Galla intrusion which could have originated this Dynasty. The examination of the tombs of the Uahka family at Qau last winter and a study of their names at different periods point to the existence of a principate holding Upper Egypt about the IXth and Xth Dynasties which brought in tombs of a hitherto unknown Nubian type. The measurements of the skulls indicate a close connexion between the Tigre skulls and Middle Dynastic Egyptian types, thus according with the Galla portrait in pointing to a southern origin. It would appear that when in the VIth Dynasty the Syrians took over the kingdom from the Egyptians, a king of the old style remained in the south, holding Nubia and Koptos. He was succeeded by invaders akin to the modern Gallas who held the Thebaid under the Libyan invaders and built the great temple-tombs of Qau. The Qau princes lasted through the Xth Dynasty, and finally one of them, aspiring to hold Thebes, took the name Amenemhat, and at the end of the Antef and Mentuhetep families occupied the throne and founded the line of the XIIth Dynasty, which, to the end, kept the features of its ancestry.

Mosquito Control at Hayling Island.—The third annual report of the Hayling Mosquito Control announces that satisfactory progress has been made in dealing with the local mosquito nuisance, although unavoidable delays have prevented the completion of the important experiments which had been undertaken on the range of flight of the salt-marsh species. The Control has, however, succeeded in obtaining the co-operation of a large number of persons by whose help it is hoped to make a detailed survey of the mosquitoes of south-east England. Such a survey should yield valuable results in elucidating the factors limiting the distribution of the various species as well as the individual range of flight. The year's work confirms the conclusion that the main pest in low-lying areas of the south coast is *Ochlerotatus detritus*. The present report is illustrated by some very fine photographs of this species, taken from a series of illustrations of the British mosquitoes which is being prepared by Mr. J. F. Marshall, the director of the Control, in his laboratory at "Seacourt," Hayling Island, Hants.

A New Crustacean.—The discovery of a representative of a new order in any group of animals is an event of interest to others besides the mere systematic specialist. This may perhaps prove to be the significance of the minute Crustacean which Th. Monod describes under the name of *Thermosbæna mirabilis* (Bull. Soc. Zool. France, xlix. No. 2, 1924, pp. 58-68). It was found at El Hamma in Algeria in a Roman bath-cistern fed by a hot spring at a temperature of 48° C. The animal is about 3 mm. in length, colourless, and without any trace of eyes, its proper habitat being doubtless in the subterranean reservoirs from which the spring takes its origin. Its general appearance is that of a small Isopod, but the fore part of the body, as far as the fourth thoracic somite, is covered by a reduced carapace, the antennules are biramous, and the five pairs of walking legs (the last two pairs are suppressed) carry large exopodites. Pleopods are absent except the first and second pairs, which are vestigial. The telson is coalesced with the last somite and the uropods are peculiar, with the inner branch much reduced. The mandibles are of the typical Peracaridan structure, and the other mouth-parts, although there are difficulties in their interpretation, are probably to be referred to the Mysidacean type. No breeding specimens were found, and it remains to be seen whether the individuals described had assumed fully adult characters and, in particular, whether the female possesses a brood-pouch of the characteristic Peracaridan structure. In many of its features, Thermosbæna shows that simplification of structure which often goes with reduction in size and a subterranean habitat. When allowance is made for this, however, it seems to form a very satisfactory link between the Mysidacea and the Tanaidacea. There are few, if any, groups of arthropods in which it is possible, on morphological grounds alone, to construct so reasonably probable a phylogenetic series as that which leads from the Mysidacea through the Tanaidacea to the Isopoda. In this series there is a place ready for Thermosbæna, either as an outlying member of one of the existing orders or, more probably, as the solitary representative of a new order to be established for its reception when we have fuller knowledge of its structure.

Amœba Feeding on Frontonia.—C. Dalé Beers (*Brit. Journ. Exp. Biol.*, vol. 1, pp. 335-341, 1924) records observations on the feeding of *Amœba proteus* on the ciliate Frontonia. An Amœba was observed to have partially engulfed a Frontonia and by its pressure to have constricted the middle region of the ciliate until the latter was forced into the form of a dumb-bell, not by the pressure of two opposed pseudopodia, but by that exerted by a collar of the Amœba's protoplasm. One half of the Frontonia was enclosed by the Amœba, the other half was exposed, and by the beating of its cilia dragged the Amœba. Later the Amœba attached itself to the microscopic slide and proceeded with the ingestion, extending its protoplasmic collar while still maintaining the pressure exerted by it upon the narrow middle portion of the ciliate, so that this portion became continuously longer and finally gave way. The part of the ciliate within the Amœba was soon enclosed in a large food

vacuole—the whole process from beginning to end occupying eight minutes. Digestion of the engulfed part lasted nearly four days. In another case observed, the Amœba carried out the same process, the pseudopodial collar being composed apparently only of ectosarc. The author points out that the observations do not accord with the view that the varied activities of Amœba are brought about entirely by changes in the surface tension of the protoplasm; it appears impossible to believe that surface tension could account for the compression of so turgid an organism as Frontonia, and for other features in the process of ingestion.

Culture of an Endamœba from the Turtle.—H. P. Barret and Nannie M. Smith (*Amer. Journ. Hygiene*, vol. iv., pp. 155-159, 1924) give an account of the cultivation of an Endamœba from the turtle *Chelydra serpentina*. The medium employed was human blood serum one part with nine parts of 0·5 per cent. salt solution. A portion of mucus containing the amœbæ from the intestine of the turtle was placed at the bottom of the culture tube in which the medium formed a column about 50 mm. deep, and the tubes were kept at room temperature or in a cool chest (10°-15° C.). The presence of numerous bacteria or of blastocystis is inimical. The growth of the amœbæ takes place only at the bottom of the tube, never in the supernatant medium. On microscopic examination numerous dividing forms were observed, but no cysts were found even in old cultures. At the time of writing (October 1923) one strain was in its sixty-seventh subculture and had been carried on for 19 months, and two others had been grown 11 months and were each in the 36th subculture. It is pointed out that this material offers an easier problem than the human Endamœbæ as the lower temperature of the culture retards excessive bacterial growth. The authors remark that Cutler is the only recent worker who has succeeded in obtaining cultures of parasitic amœbæ, and though his work has been criticised by Dobell they "cannot fail to give credit to Cutler as being the first to grow parasitic amœbæ from the human intestine." In a paper which immediately follows, W. H. Taliaferro and F. O. Holmes describe specimens of the amœba—*Endamœba barreti*—from the turtle and from the cultures.

Utilisation of Seaweed.—The Fuel Research Board of the Department of Scientific and Industrial Research has issued a Technical Paper (No. 9) dealing with the carbonisation of seaweed as a preliminary to the extraction of iodine and potassium salts. This industry has long been worked in the British Isles, and the weed has also been used as a manure. The old method of kelp-burning is very inefficient, and the work of Stanford, carried out in 1870–90, pointed the way to improved methods. The paper describes further investigations along similar lines, and an endeavour has been made to provide data which will be useful in devising a method of carbonisation of the weed in which there would be no loss of iodine and in which the gaseous products could be used for firing the retorts. A detailed description of the types of weed utilised, principally Laminaria, which contains about 0·5 per cent. of iodine, and of experiments on carbonisation, carried out on a small manufacturing scale, is given. During the nineteenth century the industry provided not a little employment, especially in the west of Scotland and in Ireland, and the report is worthy of attention.

Scarcity of Tertiary Crinoids.—In describing a new species of Balanocrinus from the Lower Miocene of Haiti (Proc. U.S. Nat. Mus., No. 2516), Dr. Frank Springer points out that this is the first stalked crinoid of Tertiary age to be described from the western hemisphere, and takes occasion to comment on the rarity of Tertiary crinoids in general. Although the number of crinoid species living to-day is probably as great as the number existing at any one time during the previous history of the earth, still the majority occur in relatively deep waters. Most Tertiary rocks are shallow-water deposits, and the inference is that crinoids assumed their present bathymetric distribution about the beginning of Tertiary time. It is also to be noted that most modern crinoids are of more delicate construction than their predecessors, and more likely to be broken up, especially in shallow water.

Physical Constitution of the Earth.—In the *Annales de Physique*, May-June, Mr. Rokuro Yamamoto develops the mathematical theory of the passage of earthquake waves through the interior of the earth, and their refraction in passing through layers of different density. He shows that there is nothing which permits the conclusion that there is a sudden discontinuity in the density at a certain depth, such as was deduced by E. Wiechert in 1897, who assumed a central nucleus of iron, with a surface layer, $\frac{1}{8}r$ in thickness, of lower density. The mathematical treatment applied to the available observations shows that good agreement is obtained by assuming a gradual alteration of density with depth, and a calculation of the time of propagation of the Japanese earthquake of September 1923 to Paris, made on this basis, gives very good agreement with observation. M. Hamy and H. Poincaré showed in 1887 that the theory of density distribution then held was difficult to reconcile with the phenomena of precession and nutation, and A. Veronet in 1912 showed that a continuous variation in density accounts for astronomical and geological observations.

Weather at Selsey Bill.—An analysis of the climate and weather at Selsey Bill, during the years 1908–23, has recently been issued by Mr. Edward Heron-Allen. The results for the sixteen years are given, not only as being of interest to residents but also as being acceptable to those who wish to know the climatic conditions afforded by the district. The extremely small mean range and variation of temperature, the well-graduated and distributed rainfall, and the great prevalence of sunshine, render Selsey an agreeable health resort. The mean temperature for the year is 50·5° F., the mean of the maximum readings is 56·7° and of the minimum 44·5°. In the eight years 1913–20, the shade temperature did not register 80°. The highest mean temperature for the year is 53·1° in 1921, the lowest 48·5° in 1909; omitting these two years of extreme temperature the range of annual means is 5·9°, from 52·8° in 1911 to 48·9° in 1917. The average annual rainfall is 29·24 in., the annual totals ranging from 38·21 in. in 1909 to 16·34 in. in 1921; the number of days with rain average 173, ranging from 194 in 1916 to 137 in 1911 and 1921. Sunshine is very prevalent, the average days for the year with bright sunshine being 310 and the average duration per day for the year 4·98 hours. A comparison with neighbouring health-resorts in the Book of Normals published by the Meteorological Office shows Selsey to have very favourable weather conditions.

New Lines in the Spectrum of Lithium.—Observing the spectrum of the positive rays (canal rays) of lithium, M. M. Morand has discovered a number of new lines, which he ascribes to an unstable modification, ortholithium, the ordinary spectrum being due to stable paralithium (*Comptes rendus* of the Paris Academy of Sciences, June 2). The new lines are given in the following table:

Wave-length.	Intensity.		
3713	4	$1s$-$2p$	first of principal series.
4814	2	$2p$-$3s$	sharp series.
4053	1	$2p$-$4s$	
3756	0	$2p$-$5s$	
5488	3	$2p$-$3d$	diffuse series.
4244	2	$2p$-$4d$	
3841	1	$2p$-$5d$	
3653	0	$2p$-$6d$	

It is assumed that in the paralithium ion, the two electrons are in crossed 1_1 orbits, while in the ortho-lithium ion the orbits are coplanar, one being a 1_1 orbit while the principal quantum number of the other orbit is two. Details are given of the energy relations between the two modifications.

COEFFICIENT OF FRICTION FOR METALLIC SURFACES.—Experiments on the friction between different metals, in various states of polish, and without lubrication, are described by M. M. Fichter in the *Comptes rendus* of the Paris Academy of Sciences, June 2. The coefficient of friction was found to diminish up to a certain point, when the polish was improved; but increase of polish beyond this point increased the friction, so that for each pair of metals used, iron on iron, brass on brass, steel on brass, copper on zinc, there was a certain critical polish, with minimum friction. With brass-brass, for example, the coefficient of friction is lowered to about 0·12, and then increases rapidly; so that to separate the two blocks may require from 1·5 to 2 kg./cm.^{2}. To obtain plane polished surfaces, the blocks were rubbed together in water containing aluminium powder in suspension. The effect of heat and pressure on the perfectly polished blocks may produce actual union (welding), so perfect that it requires the ordinary breaking load to separate them. It is suggested that in ordinary friction, in addition to the effect due to the interlocking of the roughnesses of the two surfaces, a succession of partial welds must be produced, followed by the pulling away of elements of the surfaces which have been brought into intimate contact and welded. The tangential force of sliding friction would thus depend upon the elastic reactions of the welded parts, which are stretched to the breaking point, while new welds are produced at other points of the surface.

A NEW METHOD FOR PRODUCING SINGLE METALLIC CRYSTALS.—The method described by I. Obreimow and L. Schubnikow in the *Zeitschrift für Physik*, June 4, is a modification of that employed by Tammann, who poured melted bismuth into a small test tube, covered it with infusorial earth, and allowed it to cool slowly; when crystallisation started from a single centre, and the whole of the material was formed into a single crystal. Strelkow was able to extend the method to zinc, in which the number of crystallisation centres is larger, by introducing a small "bud" crystal at the top of a crucible full of fused zinc; the bud grew to fill the whole crucible when this was cooled from the top. The authors use a glass tube, drawn out to a capillary at the bottom; the metal is melted in the tube by means of a special electric furnace, which enables the temperature of the capillary to be controlled; the air is pumped out of the upper portion of the tube, and the capillary is cooled, an air blast being used for this purpose when necessary. If the capillary is small enough, section less than 1·5 sq. mm. for zinc, 3 sq. cm. for antimony, a single bud crystal is formed in it, and grows when cooling is continued slowly at first, from the bottom to fill the whole tube. Rods from 2 to 10 mm. diameter and 30 cm. long have been obtained with tin, cadmium, zinc, antimony, aluminium, and magnesium. By varying the shape of the glass vessel, the form of the single crystal can be altered, and flat plates or cylindrical test pieces with thickenings at each end, for attachment to the testing machine, obtained.

NEW DEVICES FOR MICROSCOPES.—An exhibition of scientific instruments which is being given by Messrs. Ogilvy and Co. at 18 Bloomsbury Square, London, W.C.1, includes a large number of the most recent designs of Leitz microscopes and apparatus for photomicrographic and micro-projection work. A full range of microscopes for binocular vision suitable for all magnifications is shown. Prominent among these is the Ore Dressing Microscope, which is specially intended for the examination of granular products of concentration. The body is of the Greenough binocular type, but has several useful additions. Each tube is fitted with a revolving eye-piece holder carrying three eye-pieces which afford magnifications of 10, 15, and 20 respectively. Below the eye-piece a slot is provided for the insertion of a ruled glass plate, by means of which the number and size of the grains may be determined. The optical portion of the instrument may be moved in two directions at right angles to one another and to the central axis of the microscope, so as to cover an area of 5×5 cm. The grains to be examined are placed on a glass plate, also divided into squares, in a mount which fits the opening in the stage. Another noteworthy exhibit is the anti-vibration device with which the new Leitz photomicrographic camera is fitted. The optical bench, which carries the microscope, camera, and illuminating system, is mounted on springs which allow it to vibrate freely, the relative positions of the various components on the bench remaining quite undisturbed. The optical bench can be clamped to the table while the preliminary adjustments are being made, and many useful and novel devices are incorporated for simplifying these adjustments. The instruments and apparatus will remain on exhibit during the months of August and September, and may be examined by anyone interested. Demonstrations are given at 11 A.M. and 3 P.M. daily, except on Saturdays and Sundays.

FUSIBLE ALLOYS.—The name "fusible metal" is usually applied to alloys having melting points below that of tin. These are binary, ternary, and quaternary mixtures of lead, tin, bismuth, and cadmium. They are used mainly in the production of readily fusible safety plugs for automatic fire extinguisher systems, but during the War petrol tanks of complicated shape for aeroplane work were made by depositing copper on a casting of fusible metal, then melting out the latter in boiling water. In a paper in *Chemistry and Industry* for July 4, read before the Society of Chemical Industry, Dr. Budgen describes the properties of fusible alloys and communicates new experiments. None of the twelve quaternary alloys was entirely liquid below 73°, nor was any entirely solid above 65·5°. The addition of 16·6 per cent. of mercury lowered these points to 63° and 50° respectively.

THE MELTING POINT OF GRAPHITE.—The *Chemiker Zeitung* of July 15 gives an abstract of a paper read at the Bunsen Gesellschaft at Göttingen in May on the melting point of graphite. The experiments were made by Ryschkewitsch and consisted in passing a heavy current through a graphite rod with a constriction. At a certain temperature this constricted portion suddenly disappears, and kinematography shows that this is not due to a gradual evaporation. The temperature was also practically independent of pressure. Calculation shows that the melting point of graphite is about 3800° abs.

Pre-Columbian Representations of the Elephant in America.

By Dr. HENRY O. FORBES.

IN NATURE of November 25, December 16, 1915, and January 27, 1916, Prof. Elliot Smith set forth very circumstantially his reasons for supporting Von Humboldt in interpreting certain features of a Stela (known as B) from Copan in Central America, as a pre-Columbian representation of an elephant's trunk. This view was combated vigorously in NATURE of January 27 by three well-known American archæologists, Dr. Spinden, Prof. Allen, and Dr. Stozzer.

FIG. 1.—Manabi slab. (After Saville.)

Elliot Smith and his school attach the greatest importance to the correctness of the elephant-trunk interpretation, since it forms one of the crucial facts on which they rest their doctrine of the transference of civilisation from the Old — especially from Egypt and India—to the New World. According to Elliot Smith, the deity, spoken of as the "long-nosed god," "who was most often depicted upon the Ancient Maya and Aztec codices was the Indian rain-god Indra, who in America was provided with the head of the Indian Elephant," seemingly "in confusion with the Indian Ganesa."

I do not claim to have made a special study of Central American archæology, but I took the deepest interest in that of Peru during my sojourn there, and I have since followed with close attention any evidence tending to indicate culture-transfer between the two worlds.

The statements of Elliot Smith seemed on their appearance by their emphatically assured tone, supported by a drawing he gives of part of the Stela, apparently to afford evidence of a contact between East and West. Yet among many anthropologists, both in England and America, grave doubts have been expressed as to his interpretation of this feature of the monolith, owing to the extreme improbability of a totally alien mythology modifying successfully a very highly specialised and altogether different one, "including practically" (as Elliot Smith asserts) "the whole of the beliefs associated with" and the acceptance of "the worship of Indra."

During a tardy convalescence I have devoted some time to a careful study of the literature bearing on this point and of Dr. Maudsley's magnificent illustrations of the Copan monuments, without which it is impossible to form an opinion upon or criticise Elliot Smith's drawing in NATURE, November 25, 1915. The result is that I have arrived at an interpretation of the "elephant-trunk," different from his, which I submit to the consideration of archæologists. The *motif* of the deity's long nose is certainly not an Indian or other elephant's trunk, nor entirely, though perhaps partly, a macaw's beak, nor probably a tapir's snout; but I suggest with some confidence it is a feature derived from one or other of the Cephalopoda—squid, loligo, argonaut, octopus, or a combination of them. This suggestion, if accepted, will, I believe, help to elucidate much of the complicated emblems in which so many Central American sculptures abound.

The cephalopodous genera I have mentioned are all denizens of the eastern or western coasts of America, and any one of them might suitably be adopted as a motive in Maya mythology. Indeed an engraved stone slab from Manabi Island (Fig. 1), off the coast of Ecuador, shows that the squid (although here provided with spurious limbs) clearly entered into the mythology of that country, if not also into that of one or more regions of South America; for I found numerous cephalopod eyes and prehensile suckers from some specially large species in many of the pre-Inca graves I excavated in Peru. On the other hand the elephant is entirely alien to America. No nation suddenly changes its mental orientation. "Mere similarity of ornament," as Mr. Joyce very truly remarks, "means nothing when the ornamentation in question is found to symbolise beliefs of an entirely different character."

It is perhaps desirable to recall the following characters in the cephalopods for purposes of the comparisons I have instituted: their long tapering serpentiform arms provided with rows of prehensile suckers; their very strong mandibles, so remarkably similar to a macaw's beak, conspicuous in the centre of their surrounding arms; their water-discharging funnel—often absurdly nose-like—opening on the mollusc's (frequently warty) body (or mantle) or between its arms; their immense round, staring black, crescent-pupilled eyes, calculated to fascinate the superstitious and the timid. Some of the species inhabiting the west coast of America possess arms a score of feet in length and mandibles far larger than any macaw's—formidable and terrorising animals if unexpectedly encountered. Members of the ten-armed section of the group have two tentacles longer than the others, terminating in an expanded club arrayed with four rows of suckers.

My interpretation of the Stela will be more easily followed if I first direct attention to a lintel repre-

FIG. 2.—Serpent-bird, from Tikal. (After Maudsley and Joyce.)

senting the "serpent-bird" from Tikal, well pictured as Fig. 17, p. 55, of Mr. Joyce's excellent "Guide to the Maudsley Collection of Maya Sculptures in the British Museum." This lintel (Fig. 2), according to Prof. Elliot Smith, reproduces "a highly Americanised representation of the 'winged disc and serpents [seen over the doors of Egyptian temples].'" Here "the god's face now replaces the disc as in some of the Asiatic derivatives of the Egyptian design. . . . A striking confirmation of this interpretation (*i.e.* the conventionalisation of the serpent's 'body' into a simple cross) is supplied by Maudsley, who has shown that the pattern below the cross" (which I have

lentified as the snake's body) " is really a very highly onventionalised serpent's head reversed." It is ith great diffidence that I venture to differ from so istinguished an authority on Central American rchæology as Dr. Maudsley. If, however, he and ther interested archæologists will follow the interetation I submit here, I hope it may prove as conincing to them as to myself.

The interpretation which I would submit is: The ikal lintel represents, in its central part, neither nore nor less than a slightly specialised argonaut or ctopus, with its beak displayed in the centre of its adiating tentacular arms, representing the " god's ace." Over it two round eyes glare out under a trongly marked corrugated " superciliary ridge." his ridge is the fleshy upper margin of the mollusc's nouth, which continues into its under-margin, ormed by a fleshy band, seen resting upon two avian arsi and toes. This lower fleshy oral border, marked y three circular pedunculated discs representing ontracted tentacles on the margin of the mouth, ives origin, right and left, to a clearly defined tentacle, n which are depicted the prehensile suckers of the nollusc in the form of raised circular knobs, and erminating in a hook-like tip. On right and left he oral marginal angles are largely concealed by vhat may be termed " ear " ornaments (with their endants), from behind which issues, on each side, a ong massive arm, extending horizontally in somewhat ngular undulations until it reaches the commencenent of the conspicuous feathered extremities of the intel, where it bends downward and outward, and nds in a hook-like tip (as in the long arm of Rossia). Along its length is sculptured an interrupted series f round elevated discs, representing prehensile entacular suckers.

Starting from the same point (but in front of his larger tentacle) there can be identified another rm, coiling downwards, with a serrated margin owards its termination, and displaying the usual uckers, coiled end, and characteristic hook-like tip. mmediately above the " ear " ornament a very short, losely coiled-up, contracted arm takes origin from he margin of the mouth, while a stage higher on the intel is seen stretching upward a very prominent rm serrated on its under margin (as in some living pecies), broadening towards its free end, and exhibting conspicuously the usual suckers. This tentacle rises on each side out of the black-edged upper oral nargin of the mollusc above the eyes, while from behind it arises yet another, easily traced by its suckers. This latter extends horizontally in the background (having attached to it the wing-coverts and quills of the feathered extremities of the panel) as far outwards as the curious mace-like objects (seen at the inner edge of the feathered area), where it descends in a wide sweep in rear of the longest horizontal arm, to terminate in a scroll which appears below its lower border in a double-hooked tip. Above the flat-ended arm still another, short and closely coiled, takes rise. Its prehensile suckers begin, in a row of circular knobs, beneath the centre of the " chin " of the small central face, on the upper edge of the lintel, and continue onwards (beneath a space-filling detail) along the coil of the tentacle. Finally, behind this detail on each side arises an arm more robust, stumpy, and even " elephant-trunk "-like than the others, the prehensile suckers of which follow along both " cheeks " of the small " face." In all, seven pairs of tentacular arms surround the parrot-mandibled mouth of this design. The digits of the avian foot beneath the lower oral boundary belong to the bird the feathers of which form the terminal ornaments of the lintel. One can easily imagine that the Maya artist, finding a marine creature with a beak so macaw-like, would feel impelled to add some avian concomitants to his sculpture. He obviously took as his model for them the bird on the relief in the Palenque Temple of the Foliated Cross (Joyce's Guide, Fig. 13).

The lintel, therefore, if these interpretations be accepted, represents not " a serpent's head reversed," but an octopus with its beak displayed, as in Nature, amid its tentacular arms, and should be designated rather a feathered octopus than a " feathered snake." In any case, this sculptured design presents in no detail the remotest suggestion of an elephant or, to my vision, of a serpent, nor does it owe any inspiration to Egypt, India, or Asia; it is purely of Maya origin.

If, bearing in mind the interpretation above suggested of " the arms," " tentacular discs," and " body outline " in the " feathered snake," a close examination be made of Plate V. of Mr. Joyce's Guide where the head of the Death-god is pictured, I venture to think a strong confirmation of a cephalopod being a Maya motive will be admitted, for upon it (Fig. 3)

Fig. 3.—Head of Death-god, face of altar-table, Copan. (After Maudsley and Joyce.)

two squids quite unspecialised are clearly sculptured. The " face of the god " anthropomorphised in having human teeth conspicuously exposed by the absence of fleshy lips, takes the place of the parrot-beak of the mollusc, and is completed by a nose with two nostrils—probably derived from the sepuncle of the cephalopod, the function of which would be unintelligible to the artist. Deep set beneath a strong " superciliary ridge " are two organs, which *seem* to be eyes. Yet they more probably represent the large tentacular suckers of the two massive fleshy arms curving up under them, recalling the stumpy tentacles of the Tikal lintel. I lean to the second alternative. If this be so, then the two prominent organs at the upper edge of the altar-face are to be identified as the god's eyes. The " superciliary ridge " forms the margin, fringed with short retracted tentacles, of the monster's body (the continuation of which probably extended over the altar-table), as well as the upper margin of its mouth. Of these small fringe tentacles, one is seen on each side of the " nose." The sulcus between them corresponds with a corrugation observable between the eyes of the " feathered serpent," and helps to support my suggestion that the dark line on that panel also indicates the upper edge of a cephalopod's mouth. Similar circular tubercles, on what are plainly the mollusc's mantle, occur also on the body of the squid carved on the Manabi slab (Fig. 1) already referred to, where there is no question as to its zoological identity. Close examination of the panel reveals on the extreme right of the " superciliary fringe " the trend of the edge (indistinct on the left side) of the oral orifice which, passing behind the robust arm, reappears below as the lower margin of the mouth—scalloped (by retracted tentacles) and " warted " as on the

higher part of the mantle—passing underneath what may be called mandibular teeth, then continuing upward to meet the mantle on the left side and complete its oral boundaries. It will be noted that the Maya conventionalism for representing the dermal surface of cephalopods is by circular tubercles. These are observable here on the surface of the body, on the notch of the "nose," on the "lip" between the

FIG. 4.—Stela B. Front. (From Maudsley's photograph.)

"nose" and the upper teeth, on the two robust tentacles, and on the lower oral margin. In the argonaut, the two central arms, when all are spread, are often so closely apposed as to appear a single very broad tentacle—a feature very conspicuous in the South Atlantic Bathypolypus.

My interpretation, therefore, of the morphology of this panel is that the whole of what forms here the "face" is delineated upon a much broadened tentacle, emanating centrally from the mollusc's body, so as to overhang and conceal its true mouth, where would naturally be seen its parrot-like mandibles, as in the "feathered serpent." The space to right and left of this broad, face-fashioned tentacle, is filled in by an unmistakable species of squid, the lower end of which rests on the base of the panel, while its oral end gives rise to a circle of prehensile tentacles, two coiling downwards and more than one upwards, while the central line of its mantle is marked by a row of circular warts, as on the Manabi slab (Fig. 1). A tentacle marked with suckers is coiled round each end of the bar over which the cephalopod is apparently holding on, disjoined possibly from its continuation on the altar-table. The right and left extremities of the panel are ornamented by an oblong detail, which I should not hesitate to determine—if asked to do so—as the eye of a large species of Ommatostrophes.

This altar-face panel, I argue, supplies the key to the intricate and foliated ornament in many Maya sculptures, in that the details are traceable to cephalopods of perhaps more than one species—indigenous emblems at all events, in which there is not the slightest suggestion of anything proboscidean.

Coming now to the Stela B, "famous for the realistic representation of the Indian elephant at Copan" (of which Prof. Elliot Smith, in his "Evolution of the Dragon," has reproduced a *front* view Fig. 19 from Dr. Maudsley's plate 36, in the volume on archæology in Godman's "Biologia Centrali-Americana"), we may compare the intricate details of the monolith with those in the two panels discussed above. If, however, the right and left front *edges* of the Stela had been figured, a full view of both "trunks" and other important details, not visible *en face*, could have been more instructively studied. Dr. Maudsley's photograph (in the "Biologia") is accompanied by an elucidatory diagram to render the intricate decoration of the stone more easily followed. This diagram does not, however, quite faithfully reproduce the sculpture, and as its upper portion has been used by Elliot Smith to illustrate his letter in NATURE of November 15, 1915, it is very misleading, as will presently be noted.

The feature, on both "trunks" (Fig. 4), interpreted as a nostril, due to the ignorance (?) of the Maya artist, is clearly in its shape and more or less accurately as to its position a cephalopodous eye, like that of Sepiola, situated, as it should be, on the animal's body or mantle. Turning attention now to the right-hand upper corner of the statue, we discover there Elliot Smith's "auditory meatus." On the left of the "trunk" is (as the photograph, Fig. 5, sufficiently testifies) a tentacular arm issuing from a fold of the mollusc's body (the "forehead" of the elephant) and so coiled up as in Rossia that it ends in a close circular spiral, armed throughout its length with its rows of prehensile suckers. On the right of the trunk the origin of this coiled-up tentacle ("auditory meatus") is concealed by a flamboyant bouquet of tentacles, the suckers of which are nevertheless to be seen between and behind the flambeau. This "scroll below the ear as well as the tree-like appendages above the head," are in Elliot Smith's view "parts of the conventional waves breaking around the *sea-type* of Indian Makara." Yet the elephant of the Stela is a mahout-riding species! I feel convinced, nevertheless, that the "ear-pinnæ" of Elliot Smith (arising from behind the bar-like detail on which are seated the two human figures visible on the front aspect of the monolith) are undoubtedly cephalopod arms recalling those of Cledone. They coil round beneath the "meatus" tentacle, and end in a sharp thorn-like tip (as in Rossia) projecting conspicuously from the plane of the Stela—surely an unusual appendage to an ear-flap. These tentacles, as drawn in the

FIG. 5.—Stela B. Right-hand edge. (From Maudsley's photograph.)

elucidatory diagram, unfortunately show none of the suckers definitive of their function, though they are clearly represented in the photograph. Above both these details another (rather damaged) tentacle can be traced at the summit of the monolith on each side coiling upwards and inwards from a fold of the mollusc's body (the "elephant's" head)—none of them analogous to any organ in a proboscidean.

Studying now the corresponding angle on the left side of the monolith (Fig. 6) we see a bodyless turbaned head poised on the mollusc's body (the "elephant's" neck). This is interpreted by Elliot Smith as a mahout. On the elucidatory diagram are delineated

his driver with his braceleted hand and bent arm esting on the "elephant's forehead," and also the dge of his so-called "driving-stick" and the tips of is fingers. The Stela, however, shows absolutely no uch features. Were the arm correctly drawn in the iagram, it must originate from the driver's ear, for e has no fragment of a shoulder, no body, no arms or ands—a head only—the braceleted wrist and arm re imaginary. Underneath the "mahout's" chin riginates (as on the corresponding dextral aspect) a tentacle as a closely coiled spiral (again the "auditory meatus") with its prehensile suckers. More to the left the mollusc's body gives off a second tentacle, which meets a third, coiled up reversely, all of them armed with prehensile suckers. The ridge seen in the front view, under wh ch the bent arm of the rider is drawn in the diagram, is clearly the fleshy edge of

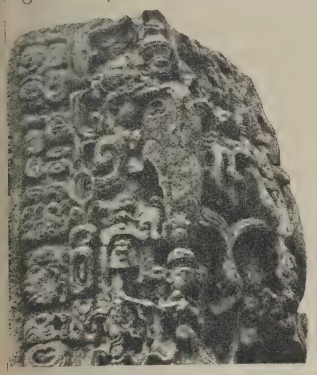

FIG. 6.—Stela B. Left-hand edge. (From Maudsley's photograph.)

he mollusc's body, corresponding to that on the ight side of the "trunk" on the right corner. From he body of the cephalopod, just beneath the "rider's" hin and above the eye which is overshadowed by t, there clearly originates from the mollusc's body a nore slender tentacle, overlaid upon the "trunk," he function of which is denoted by its prehensile uckers. How erroneously this detail has been inter- reted as a mahout's driving-stick—which he has no rm or hand to hold—an inspection of the photo- raph of the Stela itself, our sole witness, proves. The right-hand "trunk" carries no mahout and shows o "driving-stick."

Both the "trunks"—neither of which, by the way, is accompanied by tusks although Elliot Smith efers to such a feature—are, therefore, but very arge robust tentacles (one enlarged tentacular arm s not an unfamiliar character in living cephalopods) he suckers of which are indicated by the cross- natching instead of by the usual circular tuberculations, confusing perhaps macaw with cephalopod emblems. The mollusc's body, therefore, gives off around the "trunk" and "head" quite an array of tentacular arms which cannot be associated with anything in proboscidean anatomy. The supposed mahout is not the only human figure on the Stela. Two are seen in the front view, sitting between the two "trunks"; while down both its front edges, below the level of the "trunks," is sculptured a series of figures, or only heads, all of them on the Stela itself, turbaned as in the Rain-god, but none of them showing any proboscidean relationships. They have neither "trunks" to sit on nor "sticks" to drive with. If they are not mahouts, neither may the uppermost figure (seated on the mollusc's mantle) be so interpreted. As this supposed "driving-stick" turns out to be a cephalopodous tentacle, *cadit quæstio*, both as regards the trunk and the mahout.

Moreover, the turban of the "Rain-god" presents a most suggestive and interpretative "ornament." This symbol—if the two panels already discussed be kept in mind, especially that representing the Death-god—clearly represents a cephalopodous animal. On each side (the right broken) of the turban (Fig. 4) there hangs down an octopod (?) tentacle, with its free tip exactly recalling that of the longer arm in the "feathered snake" and of Argonauta or Rossia, both showing the usual circular tuberculations representing prehensile suckers. On the top of the turban and on each side a second suckered tentacle is coiled, while rising perpendicularly from the centre of its crown is seen what is quite easily resolvable into two tentacles, armed with suckers, closely applied edge to edge, as in the argonaut, but diverging half-way up to embrace a "cartouche" enclosing emblems quite in keeping with the motive—three prominent suckers, then still ascending to end in a lingulate finial.

That the cephalopod motive is a real one in South American mythology is evident from the Death-god panel and the Menabi slab; but further confirmation comes from the presence of at least one unmistakable cephalopod in the centre of the beautifully decorated reverse of the monolith (Fig. 7), where it gives off two downward coiled tentacles and two long upwardly directed arms with their characteristic terminal hook and prehensile discs. Cephalopodous emblems run riot indeed over the statue on all its sides, while not a single detail (except the mistakenly named "trunks") recalls anything in the anatomy or life of an elephant of any species, or of any creature alien to America.

It is possible, from my point of view, to interpret in the same sense the emblematic decoration in more than one of the Copan mythological designs—to name only two: the left upper vignette on the Dresden Maya Codex (Fig. 11, Joyce's Guide); and especially the left glyph in the upper row of his Fig. 6 of "Full-figure Numerals." I may add also the glyph figured by Dr. Spinden, Fig. 1, *c* in NATURE of January 27, 1916, which is combined with the macaw motive.

In his letters to NATURE referred to above, Prof. Elliot Smith avers that the scroll (representing the pinna) "was an essential part of the elephant design before it left Asia"; that "the sculptor was not familiar with the actual animal"; that he "has mistaken the eye for the nostril and the auditory meatus for the eye"; has represented "the ventral

FIG. 7.—Stela B. Part of the reverse of the monolith. (From Maudsley's photograph.)

surface of the trunk in a conventionalised manner without any adequate realisation of the true nature of the features he was modelling"; and that "having converted the auditory meatus into an eye he converted the pinna into a geometrical pattern" which "he was careful to restrict to the area occupied by a relatively small pinna that is distinctive of the Indian species." Yet, notwithstanding these many defaults of memory which are charged to the Maya sculptor,

one cannot fail to marvel that he could draw the outline of the head so accurately as to enable a zoologist to identify the original model as the Indian species and to distribute its various errors with so much acumen.

Elliot Smith's ardent supporter, Mr. Perry, provides us with a fact that increases still more our amazement: the "movement of culture," he tells us, "that set out from Egypt" [always as stressed by Rivers without their women folk] "about the beginning of the fourth millennium B.C., ultimately landed in America [after centuries spent in India, Indonesia, and Polynesia] about the beginning of our era and there founded civilisations essentially the same as that of Egypt in the Pyramid Age. . . . This movement took 3000 years, more or less, to accomplish the journey, but it can be traced with fair accuracy for thousands of miles." It is therefore scarcely surprising not only that the god Indra was confused with Ganesa and that certain features —nose, ear, pinna, turbaned rider—of the elephant head during that period became but a memory to the bearers of the heliolithic civilisation to America, but that any resemblance even of the outline of its (tuskless) head and the appropriateness of a "driver" were so well conserved, especially as Elliot Smith assures us that the motive on the Stela was not the land elephant but "the sea-elephant design of the mythical Makara [a snouted monster with large prominent tusks and a fish's tail, which never existed on land or sea, and never carried a mahout] which was the commonest form of elephant spread abroad by the sea-men of Southern India copied from an earlier model (or *picture*, according to Elliot Smith) [made thousands of years before] by some immigrant from Asia." Imagine a picture—on what material soever depicted—surviving all these millenniums among a people who were only "food-gatherers" in the palæolithic stage when the heliolithic missionaries arrived among them!

Which is more likely to have inspired the Maya sculptor, a mythical animal, the memory of which 3000 years must have paled to obliteration, the outlines, moreover, of which had never been seen by any human eye; or creatures familiar to him in his own seas, which must have excited his dread, and aroused his artistic sense?

I have to acknowledge Dr. Maudsley's photographs in the "Biologia" as the source of the above figures and his kindness in permitting me to use them, and to thank Mr. J. Edge-Partington for sketching Fig. 1 for me.

The British Medical Association at Bradford.

Tissue Culture.

At the ninety-second annual meeting of the British Medical Association held at Bradford on July 22-25, Dr. Alexis Carrel, of the Rockefeller Institute, New York, opened a discussion on the method of tissue culture and its bearing on pathological problems. The present position of tissue culture *in vitro* was clearly summarised, and considerable space was devoted to the most recent view of American workers that there are growth-promoting substances—trephones—which are secreted by certain cells of the body to minister to the nutritive wants of other cells. It is believed that leucocytic trephones play an important part in physiological and pathological processes. They secrete substances, *in vitro* and *in vivo*, and enable fibroblasts to grow readily.

Immunity.

At the same meeting, Dr. R. A. O'Brien, of the Wellcome Physiological Research Laboratories, opened a discussion on immunity, with special reference to specificity and the influence of non-specific factors. It is now a hundred years since the great French clinician Bretonneau, from a mass of observations, set free the doctrine of specificity in disease. His particular contributions referred to enteric fever and diphtheria. After long years of confusion, Dr. William Budd, in the 'sixties of last century, again placed the doctrine of specificity on a sound basis, both with respect to enteric fever and to tuberculosis. The exact experiments of Robert Koch from 1876 onwards established the specificity doctrine on an irrefutable basis, which was again extended through the discovery of antitoxin by Behring and Kitasato in 1890. Since that time every well-authenticated observation on man or animals has confirmed the specificity of infective virus.

It has been claimed, however, that certain substances which are non-specific in the sense that they have no direct or immediate affinity with the specific causes of disease, may act in a curative manner. It is the published data on this point which Dr. O'Brien has analysed. In certain instances he has subjected the question to experimental inquiry, and has been unable to find evidence that non-specific substances influence favourably specific experimental infections or intoxications. Against this is a slowly growing mass of clinical observation, which seems to point to therapeutic successes in a variety of diseases. Protein substances such as occur in milk, blood serum, and egg are claimed to be endowed with curative properties believed to be great or even extraordinary. We have recently been asked to believe that injection of milk will cure duodenal ulcers.

Many clinical observations are without much value on account of their uncritical character and the complexity of the factors involved. This non-specific therapy may be a fashion in therapeutics. At all periods there have been many such. It is said that a new drug should be exhibited while it *still* cures. It is also well not to forget that medicine still retains many of the characteristics which it had nineteen hundred years ago, when Celsus wrote, "Medicine is a conjectural art, and the nature of conjecture is such that although it answers for the most part, yet sometimes it fails."

The Microscopy of the Living Eye.

When von Graefe first saw the fundus of the living eye with Helmholtz's ophthalmoscope in 1851 he is said to have exclaimed, "Helmholtz has unfolded to us a new world! What remains to be discovered!" Indeed it is questionable whether any single physical invention has been a greater boon to medical science than the ophthalmoscope. The latest development of ophthalmoscopy is the microscopy of the living eye, the technique of which has been elaborated by several ophthalmologists but chiefly by the celebrated Allvar Gullstrand of Uppsala. Briefly stated, the method consists of illuminating the living eye by a narrow beam of light furnished by a nitra slit-lamp and condenser, and with diaphragms of various small apertures. The details of the structures so illuminated are observed obliquely either by the "teleloup" or Czapski's binocular microscope. The teleloup consists of a pair of miniature opera-glasses fixed on a spectacle frame. It gives a stereoscopic image with a magnification of about two diameters. With the microscope, nine diameters or more of magnification can be obtained.

The practical value of this new method of microphthalmoscopy formed the subject of an interesting discussion in the Ophthalmological Section, from which it is obvious that it has already yielded results of considerable scientific and practical interest. In opening the discussion, Mr. Basil Graves dealt with the physiological aspect of these results. He showed that it was possible by delicate adjustment of the illumination to demonstrate that the aqueous humour, the most pellucid of the body fluids, is not absolutely transparent, but that the range of what might be regarded as normal relucency could be determined. He has also detected varying degrees of metallic lustre in the crystalline lens, which he attributes to internal reflection from the lamellar surfaces in the interior of the lens itself.

Dr. Harrison Butler's *résumé* of the diagnostic aids which the new technique has already yielded in his hands affords an ample justification for its introduction into the practice of ophthalmology, and gives promise of further useful developments. The exact depth to which ulcerations have extended, and the localisation and extent of inflammatory processes in the cornea, can be determined with accuracy. The various forms of cataract can be detected in their earliest stages, and differentiated from one another with greater precision than heretofore. As the subsequent course and the treatment required for these several forms of cataract are widely different, it is, of course, important to be able to distinguish them early and surely. Another highly important application is in the early diagnosis of the much-dreaded sympathetic ophthalmia, by which disease many perfectly sound eyes are lost as the result of septic infection of the opposite eye. If the diagnosis is made sufficiently early, the good eye can be saved by prompt removal of the damaged eye. The detection of slight increase of turbidity of, or minute floating particles in, the fluid in the anterior chamber is the danger signal in this condition. Most of the points touched upon by the openers of the discussion are much better appreciated by demonstration than by description, consequently the interest of the meeting was focussed largely on the drawings and figures by which the papers were illustrated.

Edinburgh Conference on the Vegetative Propagation of Plants.

TO botanists and horticulturists all over the world the fame of the Botanic Garden at Edinburgh requires little comment. The collection of trees and shrubs is one of its many features; its Rock Garden alone has made it famous. So remarkable is the collection that a leading botanist from abroad was struck, not by the vast number of interesting plants, but by the fact that there are so few uninteresting ones. But the plants which meet the eye of the visitor are largely the production of that deft manipulation in the propagating pits screened from the general view, where much patient work is apt to be overlooked. Only those who have had the experience know the difficulties which so often beset the gardener who has to deal with the growing of a large representation of the world flora.

To make more generally known some of the experiences gained in the Royal Garden at Edinburgh, a well-attended Conference on the Vegetative Propagation of Plants was held on July 17 and 18 under the auspices of the Botanical Society of Edinburgh. By permission of Prof. W. Wright Smith, Regius Keeper, the meeting was conducted at the Garden, and in the large laboratory attached thereto there was on exhibition about 300 species of seed-plants, supplemented by nearly 200 photographs, illustrating various methods of propagation from stem, root, and leaf as practised by Mr. L. B. Stewart, who is in charge of the Department of Propagation. Some of the results obtained in actual practice are remarkable enough in themselves, but an added interest lies in the wide field for anatomical and physiological investigation which they throw open. It is fortunate that close co-operation exists between the Garden and the University Department of Botany, and numerous problems arising out of the experience of the cultivator are under investigation at the hands of the botanist.

Certain specific questions have already received attention and these were brought before the Conference. Thus, in the genus Clematis, it is found that stem-cuttings root freely when the cutting is made through an internode but usually not at all if cut at the node. Miss Edith Philip Smith dealt with this problem and showed that the peculiarity may be related to the large amount of sclerenchymatous tissue occurring at the nodes, since it is found that if stems are etiolated before the cuttings are prepared, rooting from the node takes place readily. Etiolation is considered to act in two ways, resulting in a softening of the mechanical tissues of the stem and in a restoration of the carbon-nitrogen ratio which is regarded as necessary for establishing meristematic activity.

Mr. L. B. Stewart dealt with the propagation of plants possessing horizontal branches, taking Napoleona and Gardenia as special cases. In the former, a non-orthotropic branch-cutting gives rise to a new individual which fails to establish a vertical shoot axis. In the course of time, however, an adventitious bud may develop from the root system to produce an ordinary orthotropic stem. In Gardenia, a cutting prepared from a horizontal branch leads to the establishment of a new plant quite distinct in growth-form from the parent. No leading shoot is formed and horizontal branching does not occur; moreover, the new individual is precocious in flowering. Mr. Stewart discussed also the results of propagation from roots, dealing especially with Pelargonium and *Acanthus montanus*. In the latter, the form of plants raised from root-cuttings is juvenile or adult according to whether young or old portions of the root are used.

Propagation by means of leaves formed the subject of a communication by Dr. R. J. D. Graham. In leaf-cuttings of dicotyledons which do not possess succulent leaves the root system is first established, followed by the development of the shoot. The time of appearance of the shoot seems to depend to some extent on the viability of the leaf. In monocotyledons, however, shoot buds appear before the formation of roots, and succulent leaves of dicotyledons behave in the same way.

Dr. Graham gave an account also of the propagation of bulbous plants by making use of the bulb scales. In Ornithogalum, Drimia, and Hæmanthus, isolated bulb scales are exposed to sunlight to allow the mucilage of the injured surface to dry. The leaf bases are then laid on sand, watered once in ten days, and within four weeks numerous bulbils begin to develop on the adaxial side of the scales. This provides a quick method of obtaining large supplies of saleable bulbs. The induced buds arise in Ornithogalum from meristematic tissue near the leaf base. In Drimia, bud formation may be induced either in the parenchyma cells of the scale or in the callus formed on the injured surface. In Hæmanthus, buds arise from the hypodermal layers of the detached leaf base.

University and Educational Intelligence.

CAMBRIDGE.—Dr. G. H. F. Nuttall, Magdalene College, has been re-elected into the Quick professorship of biology. D. L. Burn, Christ's College, has been elected Wrenbury scholar in economics.

As indicative of the growing place that organised research is holding in the University, a list of studentships awarded by the various colleges at the end of the past academic year may be of interest. At Peterhouse, W. A. Wooster (physics) and W. G. East (history); at Christ's College, A. L. Peck (classics) and D. L. Burn (history); at Magdalene College, G. E. Watts (chemistry); at St. John's College, W. H. Dew (chemistry), T. G. Room (mathematics), G. R. Potter (history), L. H. Titterton (Oriental languages), J. D. Cockcroft (mathematics), T. A. A. Broadbent (mathematics), and F. H. Constable (chemistry); at Pembroke College, H. G. Handisyde (history) and W. J. V. Ward (chemistry); at Gonville and Caius College, A. B. C. Cobban (history), R. Raper (chemistry), I. F. D. Morrow (history), W. I. Jones (chemistry), E. A. Guggenheim (physics), J. T. Irving (biochemistry), W. A. Waters (chemistry), H. T. Deas (classics), and J. C. Jones (physics); at King's College, A. Fletcher (mathematics), H. S. Kenward (classics), C. A. E. Lee (history), G. H. W. Rylands (English), and C. F. Sharman (physics); at Clare College, M. A. F. Barnett (physics). In addition, at certain colleges, notably Trinity College, scholarships are renewed for graduates doing research, so that there is a very marked move in the direction of the endowment of post-graduate research in Cambridge.

LEEDS.—An advanced course of twenty lectures on astronomy will be given on Monday evenings throughout the first and second terms of the session 1924–25, by Dr. S. Brodetsky, reader in applied mathematics, and Mr. R. Stoneley, assistant lecturer in applied mathematics and astronomical observer. Demonstrations will be given in the Cecil Duncombe Observatory. The syllabus includes lectures on such subjects as theories regarding the origin and age of the Solar System, stellar magnitudes, classification of spectra, distribution of stellar motions, double and variable stars, nebulæ, and so on. The lectures will assume such an elementary knowledge of astronomy as is represented by the popular courses given in the University. Advanced mathematical methods will not be used.

Dr. Albert Haworth has been appointed lecturer in chemical pathology. For three years Dr. Haworth has been on the staff of the Pathology Department of the Victoria University of Manchester.

LIVERPOOL.—The late Prof. Grenville A. J. Cole, Director of the Geological Survey of Ireland, and professor of geology in the Royal College of Science, Dublin, expressed a wish during his life-time that his valuable collection of separate geological papers should find a home in the University of Liverpool. After Professor Cole's death recently, his executors forwarded his collection of more than 3000 geological papers to the Department of Geology of the University.

LONDON.—Dr. Morris Ginsberg has been appointed as from August 1 to the University readership in sociology tenable at the London School of Economics.

The title of professor of electrical engineering in the University has been conferred on Mr. J. T. MacGregor-Morris, in respect of the post held by him at East London College.

The title of reader in physical chemistry in the University has been conferred on Mr. W. E. Garner, in respect of the post held by him at University College.

The title of reader in public administration in the University has been conferred on Mr. H. B. Lees-Smith, in respect of the post held by him at the London School of Economics.

The title of emeritus professor of education in the University has been conferred on Prof. J. W. Adamson on his retirement from the University chair of education at King's College.

Prof. H. R. Kenwood has resigned from the Chadwick chair of hygiene at University College as from December next. At a recent meeting, the Senate expressed appreciation of his long and valued services to the College and to the University.

The Senate has approved proposals for affording guidance to external students in their studies. The proposals are designed to meet the needs of those who are unable from any cause to follow courses of instruction either in Colleges or Institutions of the University or in other universities, or in university colleges in other parts of the country. External students finding difficulty in arranging courses of study may consult the External Registrar.

The following Doctorates have been conferred: *D.Sc. in Physics*: Harry Moore (King's College), for a thesis entitled "The Corpuscular Radiation liberated in Vapours by Homogeneous X-Radiation"; *D.Sc. in Chemistry:* A. D. Mitchell, for a thesis entitled "The Reactions of Phosphorous and Hypophosphorous Acids, with Special Reference to the Evidence they afford for the Tautomeric Character of the Acids," and other Papers; *D.Sc. in Physics:* A. M. Mosharrafa for a thesis entitled "The Quantum Theory of Radiation," and other papers.

MANCHESTER.—The following appointments have been made: Reader in surgical pathology, Mr J. Howson Ray; Lecturers in surgical pathology, Mr. P. R. Wrigley and Mr. Garnett Wright; Assistant lecturers in chemistry, Mr. Wilson Baker and Mr Bernard Cavanagh; Demonstrator in physiological chemistry, Dr. P. W. Clutterbuck. Prof. S. J. Hickson has been reappointed to the chair of zoology for a further period of two years.

ST. ANDREWS.—The Royal Commissioners for the Exhibition of 1851 have, on the nomination of the University Court of St. Andrews, awarded an industrial bursary of from £140 to £175 to Mr. Frank Gardiner Forbes, a student of engineering in University College, Dundee.

WALES.—Dr. E. H. Kettle has been appointed professor of pathology and bacteriology in the Welsh National School of Medicine (University of Wales), Cardiff.

SIR GILBERT T. WALKER, who has recently completed a period of about twenty years' service as director-general of Indian Observatories, has been appointed professor of meteorology at the Imperial College of Science and Technology, South Kensington, in succession to Sir Napier Shaw, who is retiring on August 31.

THE Higher Education Sub-Committee of the London County Council is recommending the Education Committee to award Robert Blair Fellowships, each of the value of 450*l*., to Mr. G. Bird and Mr. J. d'A. Clark. Mr. Bird, who is now with the Westinghouse Brake Company, will investigate signalling and train control problems in the United States, while Mr. Clark, who is at the Sittingbourne Paper Mills,

proposes to study the production of wood pulp in the large pulp mills of Canada.

THE Ramsay Memorial Fellowship Trustees have made the following awards of new fellowships for the session 1924–25, the place at which the award is tenable following the name of the Fellow in each case: British Fellowship of 300*l.* to Mr. S. W. Saunders—University College, London; Glasgow Fellowship of 300*l.* to Mr. A. Robertson—University of Manchester; Danish Fellowship of 229*l.* to Mr. K. J. Pedersen—University of Bristol. The following fellowships have been renewed: Dr. S. Coffey (British Fellowship)—University College, London; Dr. A. Titley (British Fellowship)—University of Oxford; Mr. Thomas S. Stevens (Glasgow Fellowship)—University of Oxford; Dr. Miguel Crespi (Spanish Fellowship)—University College, London; Dr. J. Kalff (Netherlands Fellowship)—University of Manchester; Dr. H. Weiss (French Fellowship)—Davy-Faraday Laboratory, Royal Institution; Dr. E. Boomer (Canadian Fellowship)—University of Cambridge. Sir Robert Robertson has been appointed a member of the Ramsay Memorial Advisory Council in succession to the late Sir James Dobbie.

IN "The Londoner's Education" (London, Hodder and Stoughton, pp. 58, 9*d.*), the Education Officer of the L.C.C. presents a popular account of the services of the Council as Local Education Authority, this being one of a series of handbooks "on the L.C.C. and what it does for London." The publication of these booklets is a new departure—interesting both as a means of promoting intelligent interest on the part of the citizens of London in the work of their local government and as a commendable example of municipal advertising. The writer lays stress on the admirable progress made in the field of elementary education and the wonderfully complete provision for defective and tuberculous children, London being in this respect able to challenge comparison with any city in the world. The expenditure on schools for these unfortunates is 4 per cent. of the total cost of the education service. The most remarkable thing about the appropriations of funds to the various kinds and grades of education is that the annual grants to the University of London and colleges and polytechnics for education of university standard amounts to only 0·7 per cent. of the total.

IN the early part of this year the Governing Body of the Imperial College of Science and Technology was enabled, by generous donations from the Rt. Hon. Sir Arthur Acland and Sir Otto Beit, to establish a scheme of ten Dominion scholarships for research work in science tenable at the College during the academic year 1924–25, open to university graduates in the several Dominions and in India. With the co-operation of the India Office and the Colonial Office respectively, appointments to these scholarships have now been made by the respective Governments as follows: *India*: Mr. Sarbbanisahay Guha Sircar (Calcutta University), and Mr. A. S. Gancean (University of Madras). *Australia*: Miss M. I. Collins (University of Sydney) (for work in economic botany, including forestry), and Mr. A. S. Fitzpatrick (University of Melbourne) (for work in applied chemistry, specially in relation to fuels). *Canada*: Mr. Armand Circe (École Polytechnique, Montreal), and Mr. R. J. Henry (University of Toronto). *New Zealand*: Mr. H. L. Richardson (Victoria University College, University of New Zealand), and Mr. H. O. Askew (Canterbury College, University of New Zealand). *South Africa*: Mr. Hans Pirow (for mining engineering), and Mr. Lawrence P. McGuire (for plant physiology).

Early Science at the Royal Society.

August 3, 1664. The experiment of the velocity of descending bodies was tried with three leaden balls of different sizes. The height of their descent was sixty-one feet. Mr. Hooke was desired to find some convenient place in Westminster or Paul's for the prosecution of these experiments in a place free from wind.

August 4, 1686. A letter of Mr. William Molyneux of Dublin, to Mr. Halley, was read, wherein he owned himself fully satisfied of the performance of Mr. Hooke's level; promised what account he could of the tides on the coast of Ireland, and gave his sentiments about the properest way for actual mensuration, in order to survey a degree of the earth.

August 5, 1663. Sir Gilbert Talbot received the thanks of the Society for sending them the mace, which his majesty had given them, without taking any fees.—Sir Robert Moray produced again the stones taken out of the Earl of Balcarre's heart, and desired that the figure of them might be drawn; and Dr. Wilkins moved, that it might be taken in plaister: the care of both which was committed to Mr. Hooke.

1682. Ordered—That the list be printed with several titles distinguishing all the fellows . . . and that a little mark be made before the names of such as have been benefactors, and such as frequently account for their arrears: and that the president intimate to the Society, that he hopes they will esteem such, who shew their affection to the Society this way, as more properly eligible for office.

August 6, 1662. Mr. Wilde was desired to communicate his method of laying leaf-copper without tarnishing.—Dr. Charlton was desired to give in writing the account of the boy killed by lightning.—Dr. Goddard brought in an account of his experiments of weighing glass canes with the cylinders of quicksilver in them, according to the Torricellian experiment; which was ordered to be registered.

1668. A microscopical observation devised by Mr. Hooke, was made on a little lump of charcoal of fir-wood, in which appeared here and there interstices or partitions intersecting the great pores. Several of the members saw it and were satisfied.—Several queries were proposed about the texture of trees.

August 7, 1661. Mr. Henshaw produced a stone called "Astroites" or "Lapis stellaris," of which the following account is registered; That it moved with a little vinegar upon a declining plate several times repeated; and that it was observed, that the stone grew somewhat hot, and brak at the top. It is to be remarked, that there are two sorts of "Astroites," the one marked with starry spots, and the other stellate in its form.—Dr. Wilkins was desired to try salt-petre in water, to see if it increased in bulk.

1679. The Society adjourned for the ensuing vacation, not to meet again till summons given; but such members as pleased to meet to discourse in the mean time, might do so at the repository or library on Thursdays in the afternoon, where there would be some entertainment for them.

August 8, 1666. The president reported, that the experiment mentioned April 18, 1666 by Mr. Povey, of a new way of laying on colours, had been made that morning by Mr. Streeter at his house before himself, Sir Robert Moray [and others] viz., that an egg was beaten yolk and white together, with a few shreddings of a fig-tree branch, whereby the egg was reduced into an oily substance, without any tenacity or ropiness, so that it would be ductile, and fall on the pencil like oil.

Societies and Academies.

LONDON.

Faraday Society, July 7.—Sir Robert Robertson, president, in the chair.—G. R. D. **Hogg**: A note on the conduction of heat down the necks of metal vacuum vessels containing liquid oxygen. Approximate methods are given for calculating the "neck loss" of metal Dewar flasks containing liquid oxygen. These may also be used for determining the most suitable dimensions for the inner neck of a metal Dewar flask, the other dimensions of which are known.—C. L. **Haddon**: The mechanism of setting of calcium sulphate cements. There are fundamental differences in the hydration processes between plaster of Paris, flooring plaster and anhydrite. Further evidence in favour of Desch's theory of crystal thrust as the cause of expansion is put forward. There is a similarity between the coherence of calcium sulphate cements and that of metals.—J. J. **Doolan** and J. R. **Partington**: The vapour pressure of tellurium. The vapour pressure of sulphur has been determined in various ways, and at least one determination of that of selenium has appeared. The vapour pressure of tellurium, however, has, apparently, not previously been measured. Its value, at least approximately, has been determined at different temperatures.—E. E. **Turner** and W. H. **Patterson**: Cryoscopy in sodium sulphate decahydrate. The molecular weights of a number of sodium salts have been determined, using sodium sulphate as cryoscopic solvent, a method first investigated by Löwenherz, whose results have, in general, been confirmed. Abnormal results were obtained for the molecular weights of sodium oxalate and borax. The low result for the former substance is not due to solubility effects, whilst the molecular weight obtained for borax is in good agreement with the value obtained by Boutaric, Chauvenet, and Nabot, using sodium thiosulphate as solvent.—D. B. **Macleod**: The viscosity of binary mixtures.—J. B. **Firth** and F. S. **Watson**: The catalytic decomposition of hydrogen peroxide solution by animal charcoal; the production of highly active charcoals.—A. J. **Allmand** and A. N. **Campbell**: The electro-deposition of manganese. The best conditions for the electro-deposition of pure manganese consist in the electrolysis of a solution containing manganous and ammonium sulphates (the catholyte) separated by a diaphragm from the anolyte (ammonium sulphate solution), the H· concentration being kept at 10^{-6} to 10^{-8} by the regulated addition, as required, of sulphuric acid or of ammonia. The temperature is 30° C. and the current density at the cathode 10-15 amps./d.m. The rotating aluminium cathode has a burnisher lightly pressing against it. Electrolyte manganese contains a considerable quantity of dissolved hydrogen, which is not, however, responsible for its brittle nature.—J. **Grant**: Concentration-cells in methyl alcohol. Part II. Solutions containing tetraethyl ammonium iodide.—F. H. **Jeffery**: The electrolysis of solutions of potassium oxalate with a tin anode, and an electrometric determination of the constitution of the complex anions formed. Electricity passes from anode to anolyte in accord with the equation—

$$Sn + 2C_2O_4'' - 2\ominus = \{Sn(C_2O_4)_2\}''.$$

A solid phase corresponding with this complex ion,

$$K_2\{Sn(C_2O_4)_2\}.H_2O,$$

can be isolated. When the tin anode is coated with finely divided metal and the products of electrolysis allowed to accumulate on it, anodic oxidation takes place probably in accord with the equation—

$$\{Sn(C_2O_4)_2\}'' + C_2O_4'' - 2\ominus = \{Sn(C_2O_4)_3\}''.$$

A solid phase derived from tetravalent tin is formed, but it has not been determined whether it is of the form $Sn(C_2O_4)_2$ or $K_2\{Sn(C_2O_4)_3\}$. No tin is deposited on the cathode during this stage. The anode potential remains constant for a wide range of current density provided the anode be kept free from finely divided metal and the products of the electrolysis: failing this precaution it may rise to more than nine volts referred to the normal hydrogen electrode as zero, the current being 0·1 amp. The Darwin thread recorder has been adapted to the measurement of variations of the electrolysis current and also the time-integral of this current. It shows the rapidity of the change from the stage of the formation of the stanno complex alone to the stage of anodic oxidation.—F. J. **Fraser**: An improved form of Crook's elutriator.

CAMBRIDGE.

Philosophical Society, July 14.—Mr. C. T. Heycock, president, in the chair.—E. V. **Appleton**, K. G. **Emeléus**, and M. **Barnett**: Some experiments with an α-particle counter. The "wave-form" and intensity of the transient impulses resulting from discharges stimulated by single electrified particles have been determined using a cathode-ray oscillograph. The nature of the impulse is determined largely by the capacity and resistance of the system. The potential impulse normally detected by string electrometer methods is proportional to the current responsible for the re-charging of the electrostatic capacity of the counter after the rapid discharge of the capacity initiated by the electrified particle. When the pressure in the ionisation chamber is made less than that at which self-restoring action is possible, persistent oscillations are found. These represent the periodic charging of the counter capacity after its periodic discharge between the point and the plane. The impulses normally produced by α-particles are thus represented by one unit of the sustained oscillation. The total quantity of electricity circulating round the system when an α-particle enters the chamber is, in normal cases, of the order of 10^{-10} coulomb, but in low resistance circuits may be made 10^{-6} coulomb. The "energy trigger ratio" of the counter for α-particles, which represents the ratio of the energy released in the system to that of the electrified particle acting as stimulus, is normally of the order of 10^5, but may be made as high as 10^9.—J. E. **Littlewood**: On the zeros of the Riemann zeta function.—S. **Lees**: A case of steady flow of a gas, in two dimensions.—P. A. M. **Dirac**: Note on the Doppler principle and Bohr's frequency condition.—B. M. **Sen**: The applicability and deformation of surfaces.—E. C. **Titchmarsh**: A system of linear equations with an infinity of unknowns.—J. B. S. **Haldane**: A mathematical theory of natural and artificial selection. Part II. Expressions are found for the effects of various degrees of self-fertilisation, inbreeding, assortative mating, and selective fertilisation, on the composition of Mendelian populations, and the progress of natural selection in them.—H. W. **Turnbull**: The vector algebra of eight associated points, of three quadric surfaces.

CALCUTTA.

Asiatic Society of Bengal, July 2.—Gilbert T. **Walker**: On the wings of gliding birds. A peculiar feature in the structure of the wings of gliding birds is comparable to a device adopted in the construction of Handley-Page aeroplane wings.—E. W. **Gudger**: The sources of the material for Hamilton-Buchanan's "Fishes of the Ganges," the fate of his collections, drawings and notes, and the use made of his data.—

L. M. **Davies**: Notes on the geology of Kohat, with reference to the homotaxial position of the salt marl at Bahadur Khel. The beds at Kohat are homotaxial with the beds at Bahadur Khel.—Baini **Prashad**: Revision of the Japanese species of the genus Corbicula.—W. **Ivanow**: (1) More on the sources of Jami's 'Nafahat.' A summary description of the rare work, Risāla-i-Iqbāliyya, containing an account of the discourses of 'Alāu'd-Dawla Samnānī (d. 1336). (2) Imam Ismail. New information concerning Ismail, the sixth Imam of the Ismailiyya. It was found in a rare and early book on Shi'ite tradition, by Kashī, dating from the tenth century.—K. N. **Dikshit**: Two Harsola copper-plate grants of the Paramara Sikaya (II.), V.S. 1005.—Amareshvar **Thakur**: Jail administration in ancient India. A brief review, mainly based on data furnished by the Buddhist Jātakas and Kautilya's Arthasāstra, drawing the conclusion that a humane element was not wanting in ancient Indian criminal justice.—Sir Gilbert T. **Walker**: A note on Indian boomerangs. Description, with illustration, of a new species, called *Kâtar*, used as a throwing stick by the Bhils.—Paul **Tedesco**: The dialectical position of Ormurī.—N. G. **Majumdar**: A list of Kharosthī inscriptions.—H. Srinivasa **Rao**: Note on a brackish-water actinian from Madras. A form apparently new to science, probably closely allied to *Pelocoetes*, which was collected in 1922, was described.—H. **Chaudhuri**: *Oedogonium Nagii sp. nov.* Found at Lahore, developing in a bottle containing a collection of Zygnemas.

OTTAWA.

Royal Society of Canada (Section V., Biological Sciences), May 19-22 (Annual Meeting at Quebec).—F. C. **Harrison** (Presidential Address): Historical review of the red discoloration of foodstuffs.—A. H. Reginald **Buller**: (1) Luminous leaves; (2) *Sphærobolus stellatus* and the dispersion of its spores by herbivorous animals.—C. W. **Lowe**: The fresh-water algæ of Central Canada.—B. T. **Dickson** and G. A. **Scott**: Identity of the organism causing black-dot disease of the potato, Part I. and Part II.—B. T. **Dickson** and W. L. **Gordon**: The effect of various smut control treatments on the germination of oats.—C. D. **Kelly**: The bacteriology of the Kingston cheese.—N. S. **Golding**: A study of the moulds in blue-veined cheese.—A. G. **Lochhead**: (1) Microbiological relationships in frozen soils; (2) Psychrophilic soil bacteria.—G. W. **Scarth**: The toxic action of distilled water and the antagonism to it of cations.—A. B. **Macallum**: The origin of karyokinesis.—A. T. **Cameron** and J. **Carmichael**: After-effects of feeding thyroid to young rats.—A. T. **Cameron**: (1) The action of absorbable intestinal toxins on metabolism; (2) The cranio-facial axis of Huxley—Pt. I., Embryological considerations.—J. G. **FitzGerald** and Dorothy G. **Doyle**: A further study of the question of utilisation ("fermentation") of saccharose by *B. diphtheriæ*.—J. J. R. **Macleod**, J. **Hepburn**, J. K. **Latchford**, and N. A. **McCormick**: The effect of insulin on the percentage of sugar in blood from different regions of the body.—J. J. R. **Macleod**, E. C. **Noble**, and M. K. **O'Brien**: The influence of insulin on the glycogen content of the liver and muscles during hyperglycæmia.—G. S. **Eadie**, J. J. R. **Macleod**, and M. D. **Orr**: The soluble carbohydrates of liver and muscle and the influence of insulin on them.—F. N. **Allan** and S. S. **Sokhey**: Further observations on depancreatised animals.—S. U. **Page**: The effect of insulin on chloridzin diabetes in dogs.—J. **Markowitz**: The behaviour of the diastases in diabetic animals treated with insulin.—Frederick R. **Miller** and H. M. **Simpson**: Viscero-motor reflexes.—R. **Miller** and R. A. **Waud**: Pulse and cardiac records obtained with electropolygraph.—G. A. **Ramsay**: Amplification of heart sounds by radio apparatus.—J. **Miller**: Classification of tumours arising from the trophoblast, with illustrative cases.—C. McLean **Fraser**: *Acaulis Primarius*, Stimpson.—A. G. **Huntsman**: Some results of the Belle Isle Strait Expedition, 1923.—R. H. **McGonigle**: The distribution of pile borers on the Canadian Atlantic coast.—A. H. **Leim**: Certain features in the life-history of the shad.—A. G. **Huntsman** and M. I. **Sparks**: Resistance of marine animals to high temperatures, and their distribution in Nature.—C. H. **O'Donoghue**: A list of the Nudibranchiate Mollusca recorded from the Pacific coast of North America, with a note on their distribution.

VIENNA.

Academy of Sciences, January 10.—Kurt **Ehrenberg**: On the development of the base of the skull in cave bears from the Drachenhöhle near Mixnitz. The communication is chiefly concerned with the confirmation of a hitherto unobserved epiphysis formation in the lower half of the posterior head condyles of the cave bear (*Ursus spelaeus*), which appears during the second year of life. Later the epiphysis fuses completely with the original condylus occipitalis. Its formation is conditioned by a change in the attitude of the skull, a downward inclination of the skull as it becomes heavier, and appears to have arisen only in the males.—A. **Skrabal** and H. **Airoldi**: On the rate of hydrolysis of ethyl ether.—A. **Skrabal** and M. **Baltadschiewa**: On the rate of hydrolysis of orthoacetic-ethyl ether.—R. **Andreash**: Note on the paraban acids.—R. **Andreasch**: On the carbamide and guanidin derivatives of the sulphur-substituted fatty acids; Part II.—E. **Müller**: On combined conic sections of conic section pencils.—K. **Ehrenberg**: On the development of the anterior region of the skull of the cave-bear from the Drachenhöhle near Mixnitz.—A. **Pisek**: The development of the anthers and the meiotic division of the pollen mother cells in the juniper-mistletoe, *Arcenthobium Oxycedri*; the structure of the anthers and the number of chromosomes in the cells of *Loranthus europæus*. The anther of Arcenthobium is regarded as equivalent to a microsporangium. The meiotic division of the pollen mother-cells sometimes shows disturbances caused by insufficient nourishment of the parasite by the host plant.—R. **Kreman**, R. **Kienzl**, and R. **Markl**: Electrolytic conduction in fused alloys; Part III., The electrolysis of lead-cadmium and of lead-sodium-cadmium alloys. With currents of about 1 amp. per sq. mm., an increase in the concentration of lead was found to occur at the anode and of cadmium or sodium respectively at the cathode.

January 17.—R. **Kreman**, R. **Müller**, and H. **Kienzl**: Electrolytic conduction in fused alloys; Part IV., The electrolysis of mercury-sodium alloys. The increase in concentration of sodium at the cathode and of mercury at the anode was found to grow with the density of the current to a maximum of about 9 per cent.—R. **Kreman**, R. **Müller**, and R. **Ortner**: Electrolytic conduction in fused alloys: Part V., The electrolysis of mercury alloyed with potassium, calcium, and cadmium. An increase in the concentration of potassium, calcium, and cadmium is observed near the anode, the effect increasing with the density of the current.—L. **Moser** and A. **Brukl**: On solid compounds of hydrogen and arsenic. The formation of solid As_2H_2 according to Reckleber and Scheiber is confirmed. A new solid compound, tetra-arsenic hydride As_4H_2 was obtained by the use of weak oxidising agents on gaseous AsH_3.—K. **Schnarf**:

Remarks on the position of the genus Saurania.—K. **Keissler**: Fungi novi Sinenses a H. Handel Mazzetti lecti II.

January 24.—H. **Micoletzky**: Final report on free-living nematodes from Suez. The Mediterranean and the Red Sea appear to have more nematodes in common than the Mediterranean and the North Sea.—G. **Götzinger**: Morphological studies after the great landslide of the Gras-mountain at Oberwang in Attergau.—H. **Handel-Mazzetti**: Plantæ novæ Sinenses diagnosibus brevibus descriptæ.

February 7.—F. **Werner**: New or little known snakes from the State Museum of Natural History at Vienna. New genera of aglyptic Colubrides, *Procteria viridis* (n. sp.), South-west Africa, allied to *Pseudoxenodon*, *Pachyophis temporalis* (n. sp.), *Triænopholis arenarius* (n. sp.), *Aryrogena rostrata* (n. sp.), Argentine, *M. elegantissima* (n. sp.), *Pseudoromacer lugubris* (n. sp.), San Paolo, Brazil, *Nerophidion hypsirhinoides* (n. sp.), allied to *hydræthiops*, *Padangia pulchra* (n. sp.), Padang, Sumatra, *Eoninophis lineolata* (n. sp.), East Africa.—A. **Skrabal** and M. **Baltadschiewa**: On the rate of hydrolysis of ortho-carboxyl-ethyl-ether.—A. **Skrabal** and A. **Matievic**: The dynamical equilibrium of malic ester.—E. **Schweidler**: Studies in atmospheric electricity, No. 65, On the characteristics of the current in slightly ionised gases. The characteristic of the ions is calculated by linear recombination law and the proportionality between conductivity and the saturation deficit of the current is found to hold. The term semisaturation potential (corresponding to 50 per cent. saturation) is defined. The application to practical measurements is demonstrated.—W. **Schlenck**: Studies in atmospheric electricity, No. 66, Experimental investigations on the characteristic of the current in weakly ionised gases. With a cylindrical condenser as ionising vessel, the current-potential function was found to correspond to the linear law of recombination.—M. **Blau**: On the disintegration constant of radium A (Mitt d. Ra-Inst's No. 161). A new experimental determination gives the radioactive constant . . . $\lambda = 0{\cdot}2273 \pm 0{\cdot}0007\ \text{min}^{-1}$; the half value period was found to be $T = 3{\cdot}05 \pm 0{\cdot}009$ min.—W. **Riss**: On the composition of bröggerites and on the genetic relationship between thorium and uranium (Mitt. d. Ra-Inst's No. 162). A large number of analyses on bröggerites have proved that idiomorphic bröggerites are probably all (many of them without doubt) older than the lodes in which they are found. As there are also non-idiomorphic bröggerites, it remains an open question whether these can be used for age measurements and also whether the large differences in the ages of the lodes found in this way are real. The results do not contradict the assumption of a genetic relationship between thorium and uranium.—E. **Lohr**: On the comparison made by Fr. Schenner between the Jaumann's theory of gravitation and observations.—G. **Flumiani**: On a dimethyl - tetroxy - anthrachin. — K. **Brunner**, W. **Seeger**, S. **Dittrich**: Diacyamine.—A. **Tauber**: On the integration of linear differential equations, IV.—O. **Storch**: Studies on dragonflies from the biological station at Lunz, Lower Austria, and the second Zoological Institute of the University of Vienna. *Somatochlora metallica*, an anisopterate odonate, lays its eggs in the earth inserting its ovipositor in the intervals of its flights over water. The Odonata anisoptera are not gliding air-machines; they make the best use of the freedom of movement which their mode of flight permits, lifting themselves straight into the air and performing all sorts of evolutions during oviposition.—F. M. **Exner**: On the release of cold and warm outbursts in the atmosphere.—F. **Feigl**: Contributions to the study of the relationship between the grouping of atoms and specific affinity, Part I.

February 17.—P. **Weiss**: (1) Regeneration o whole from half the cut surface of an extremi *Triton cristatus* (from the Institute of E mental Biology of the Academy of Science, Vie If the leg be split and both parts shortened by am tion, a whole foot will regenerate from the ha surface when the second half regenerates notl otherwise regeneration of a whole foot occurs, di between the two stumps, forming a split extremi merging into one blastema. (2) Regeneration fr double cut surface of an extremity in *Triton cris* When the arm is artificially bent in such a way the radius lies parallel to the humerus, fixed in a position, and the elbow cut off, exposing tw surfaces, one from the humerus, one from the arm, a symmetrical structure regenerates, the reg ating part from one cut surface being the mirror i of the other.—I. **Sciacchitano**: The stage in dopa is formed in the cocoon of the moth *Lop pini* (from the Institute for Experimental Biolo the Academy of Science, Vienna). Dopa, *i.e.* d phenyl-alanin, is only produced in the cater during spinning and is already lost when the st pupation is attained.—L. **Kober**: Contribution t geology of anomalies in the gravitational fo A. **Köhler**: Petrographic-geologic observations i south-western forest district.—L. **Kölbl**: Report petrographic-geological studies in the western p the forest district in Lower Austria.—L. **Waldm** Preliminary report from the survey of the Mor district to the south of the Eggenberg-Siegsmun berg railway line.

Science and Life.[1]

THERE has been no niggardliness in the intellectual menu provided for the Toronto visit of the British Association. There is plenty to masticate, and there are also delicacies. But the metaphor is dangerous, and we let it drop. The president, Sir David Bruce, strikes the humane note, "Science for Life," in his fine address. In the long run, man wins against microbe ; thus Malta, once the most deadly of foreign stations, becomes a health resort ; Malta fever is beaten in the first round. Anti-typhoid inoculation was one of the outstanding victories of the war, and the anti-toxin treatment of tetanus was another. The prevention of tuberculosis depends fundamentally on improved environment and on the education of the people in the art of health. The protozoal infectious diseases, like the bacterial, are being mastered—witness sleeping sickness and malaria. Successful attacks are being made on the undetermined group of infectious diseases, probably due to "filter-passer" germs, such as trench fever and typhus fever. Here the zoologists have to be thanked for their discovery and tracking of the insect and mite carriers ; and what shall we say of the attacks on deficiency diseases, whether the standard of victory bears the legend "vitamins," "balanced nutrition," or "endocrine glands"? "Man has come into his heritage."

Prof. J. W. Gregory, addressing the Geography Section, brings us back to the idea of "Control." He seeks to show that, if due care be taken, the white man is not physiologically disqualified from manual labour in the tropics. This simplifies inter-racial problems, as it provides an additional outlet and a spacious home for the European race. The world has reached its present position by help of each of the three great races, and it still needs the special qualities of each of them—the contemplative Asiatic, who founded religions ; the artistic Negro, who probably gave the world the gift of iron, and the administrative European, who has organised the brain power of the world. But "the affectionate, emotional Negro, the docile, diligent Asiatic, and the inventive, enterprising European do not work at their best when associated in mass." Individual association there must be, but co-residence *in mass*—that way lies trouble. But will the clock stand the implied turning back of its hands, and will our hygienically resolute swarming into the tropics stop short of being massive ?

In his careful address to the Anthropology Section, on health and physique through the centuries, Dr. F. C. Shrubaill showed that Britain is *not* going to the dogs. "A pessimistic view of the physical or mental condition of the people of England is unnecessary and unfounded." Stature and weight are not less than in the days of Agincourt ; the general health of the nation is better and the expectation of life longer than ever before ; the real increase of the unfit is much less than has been assumed on a priori arguments ; the dysgenic tendencies of industrialism are being successfully opposed. Not that Dr. Shrubsall is satisfied with things as they are. His thesis, well documented, is

[1] The Advancement of Science, 1924 : Addresses delivered at the Annual Meeting of the British Association for the Advancement of Science (94th Year), Toronto, August 1924. Pp. iv+33+19+36+20+16+24+30+12+21+15+7+14+9+14. (London : British Association, 1924.) 6s.

that they are not nearly so bad as some Cassandras make out.

An inspiring address to the Physiology Section by Dr. H. H. Dale dealt with the progress and prospects of chemotherapy. "Science for Life" again! Chemotherapy in general is the specific treatment of infections by artificial remedies, but Dr. Dale was picturing the systematic chemotherapy which the genius of Ehrlich revealed, "the production by syntheses of substances with a powerful specific affinity for, and a consequent toxic action on, the protoplasm of the parasites, and none for that of the host." What Ehrlich was in search of were introduceable substances, which, as he said, should be maximally parasitotropic and minimally organotropic. What makes the difference is a biochemical problem still unsolved, but contributions to the reading of the riddle are rising above the horizon.

"As the biological complexity of the problem is realised, it becomes increasingly a matter for wonder and admiration that so much of practical value has already been achieved—the treatment of the spirochætal infections, syphilis, yaws, and relapsing fever, revolutionised; Leishmania infections, kala-azar and Baghdad boil, and Bilharzia infections, which crippled the health of whole populations in countries such as Egypt, now made definitely curable; trypanosome infections, such as the deadly African sleeping-sickness, after years of alternating promise and disappointment, brought now at last within the range of effective treatment."

Such achievements, we must remember, have rewarded experiment during a period—does it ever end?—when practice outran theory. What victories may be looked for when a fuller understanding affords not only tactics, but also strategy. This address will appeal to many very strongly with its Pisgah view of a Promised Land with no unconquered infectious diseases.

To the Botanical Section Prof. V. H. Blackman gave an address which does not sound like botany at all, it is so interesting. There is nothing in it about a "hortus siccus," and it is impossible not to be thrilled by the account of the unending attacks which the parasites make on the capitalists.

One of the peculiarities of parasitic diseases in plants, as contrasted with those of animals, is that the plant seems to give the same answer back to quite different invaders. Among animals, if certain symptoms appear, one can, in most cases, infer the presence of a certain parasite, but in plants a large number of infectious diseases display the same symptoms. This makes the practice of medicine among plants much more difficult than among animals. Another difference is that the acquired immunity due to one attack of a disease which is so common in animals is quite unknown in plants. Again, owing in part to the absence of a circulating blood-stream, the plant makes a local rather than a general reaction to the infectious disease.

Immunity and resistance to diseases are, of course, well known among plants, but they illustrate *natural*, not acquired immunity. There may be some physical barrier which resists the entry of the parasite, or the entry may call forth a wound reaction leading to the production of cork which checks further advance. This natural resistance may be increased by good cultivation, or Mendelian breeding may build up a plant synthetically which is resistant to various intruders, but there seems to be no hope of finding a way of endowing plants with artificial disease-resistance.

As Lord Kelvin was born a hundred years ago and as Faraday discovered the principle of the electromotor in 1821, it was very appropriate that Prof. G. W. O. Howe should address the Engineering Section on "A Hundred Years of Electrical Engineering." He told a story of fascinating interest—a story that mankind may well be proud of. It is a record of "the mastery of man over the resources of nature, and in the use of these resources to the amelioration of the conditions of life." Every one knows part of the story, but a general review is very eloquent.

"By the aid of electricity the energy of the coal of the lake or river a hundred or even two hundred miles away is transmitted noiselessly and invisibly to the city, to supply light and warmth, to cook the food, to drive the machinery, to operate the street-cars and railways." We flash intelligence to the most distant parts of the globe; we talk to our friends hundreds or even thousands of miles away; at small cost we can equip ourselves with what may almost be regarded in a new sense. "Whereas thirty years ago a ship at sea was completely isolated from the life and thought of the world, it is now in continuous communication with the land and with every other ship within a wide range."

In no branch of electrical engineering is there any suggestion of having reached a limit; rapid development is taking place in every direction.

Prof. William McDougall spoke of "Purposive Striving as a Fundamental Category of Psychology." The life of man from birth to death is one long series of purposive strivings. Even in his dreams the striving goes on. This must be recognised as an all-important aspect, corrective to the picture of man as "a bundle of mechanical reflexes, a superior penny-in-the-slot machine, whose workings are mysteriously accompanied by various 'elements of consciousness.'" The address may be described as a plea for more courage in psychology, which is spoken of as "the most concrete of the sciences."

Three of the addresses of presidents of Sections will not be delivered until Monday, August 11, so we cannot deal with them this week: they are by Sir William Bragg on the analysis of crystal structure by X-rays, by Prof. F. W. Gamble on construction and control in animal life, and by Sir John Russell on present-day problems in crop production. We are reluctantly forced to pass over here the other presidential addresses—by Sir Robert Robertson on chemistry and the State, by Prof. W. W. Watts on geology in the service of man, by Sir W. Ashley on Free Trade doctrine, and by Principal E. Barker on academic freedom in universities, but summaries of them will be found in the Supplement to this week's issue. They are as interesting and as important as those of which we have given glimpses, and Toronto cannot complain of having been offered "second best" material. There is a very high standard throughout. There is also an interesting unity, for most of the addresses come round to the fact that man conquers by understanding. The people perish for lack of knowledge; but science is for life, even for the life that is more than meat.

Where Philosophy joins Forces with Mathematics.

Substance and Function and Einstein's Theory of Relativity. By Ernst Cassirer. Authorised translation by Dr. William Curtis Swabey and Dr. Marie Collins Swabey. Pp. xii+465. (Chicago and London: The Open Court Publishing Co., 1923.) 3·75 dollars.

THE translators of Prof. Ernst Cassirer's most important contributions to mathematico-logical theory have done well to issue his "Substanzbegriff und Fonktionsbegriff" and his "Zur Einsteinschen Relativitätstheorie" together in one volume, although a considerable time interval separates the two works. The first appeared in 1910, the second in 1921, and the interval covers the formulation by Einstein of the new theory of gravitation. By presenting the two together, the philosophical significance of the principle of relativity and the intimate connexion of its mathematico-physical form with the logico-epistemological form of the philosophical problem are clearly brought out. The translation has succeeded in reproducing the clear scientific expression of the German and reads like an original English work. For an American publication there are singularly few Americanisms in the text. It is very unfortunate, however, that the word "Begriff" is not retained in the English title. The book is not about substance and function but about the concept; substance and function are meant to be adjectival, not substantival terms.

Prof. James Ward, in his recent most illuminating work, "A Study of Kant," has shown very clearly how Kant's interest in natural science and desire to discover its metaphysical basis were the original motive and directing force of his philosophy. Prof. Cassirer enables us to see the real significance of the Kantian doctrine in its relation to physical theory. The transcendental æsthetic was not, as often represented, a subjective idealism in regard to the concepts of space and time; on the contrary, it was a justification of the objective use of those concepts and intended to rationalise the Newtonian doctrine and provide a philosophical basis for the Newtonian physics. The attempt of Kant in the transcendental analytic to provide the necessary scientific categories is still more striking. It is curious to follow the complete transformation which has overtaken the chief doctrines of formal logic since he took it as the type of the perfect science, the science which since Aristotle had not had to advance or retrace a single step. This is Prof. Cassirer's starting-point. He shows how the Aristotelian logic depends on the Aristotelian metaphysics, how this accepts the substantival aspect of the world as given fact and the work of thought as discovery, and he traces the steps and stages by which in modern mathematical and logical theory, since Kant (and even before Kant, for the essential change of direction is found in Descartes and Leibniz), the whole position has been reversed.

The fundamental thought of logical idealism is most strikingly exhibited in mathematical theory. "More and more the tendency of modern mathematics is to subordinate the 'given' elements as such and to allow them no influence on the general form of proof." The concept of magnitude gives place to the concept of function; quality, not quantity, is the real foundation of mathematics. In place of the analysis of parts there appears the resolution into concepts.

How do we form concepts, and what purpose do they serve? The two questions are really one, the fundamental problem of the nature of the physical world which is the basis of physical science. Two principles seem equally insistent. One holds us firmly to concrete experience. The concept seems empty and meaningless which does not deepen and enrich our intuition. Yet when we turn to the mathematical concepts, and especially to the meaning of number, we seem to grasp this meaning completely only when thought has freed itself from seeking in concrete experience a correlative for its constructions. We are left to choose between two views of the world: either the empirical view that the only existent is what we can point to as an individual in a real presentation, or the idealist view that what really exist are intellectual structures which can never themselves be presented. Mathematics will not solve the riddle. All it can do is to lay bare the ultimate intellectual roots of our analysis of experience.

What then is the relation of mathematics to physics? The advance of theoretical physics has completely superseded the old view that measurements inhere in physical things and are just read off. The intellectual work of understanding a bare fact presented in sense-experience as an entity or empirical object only begins when the fact is replaced by a mathematical symbol. For the physicist the individual thing is a system of physical concepts. To distinguish one object from another, he must subsume it under a conceptual class. He analyses the object into the totality of its numerical constants; he does not break it up into the group of its sensuous properties. The thing changes from a sum of properties into a mathematical system of values established with reference to a scale of comparison. The constitutive parts of

the perception are left completely out of account, and the mathematical symbol which constitutes the object a member of a system is taken as the real kernel of empirical reality. It is only when we bring the given under some norm of measurement that it gains fixed shape and form and has clearly defined properties. The metaphysical concept of substance, which natural science always clung to, has been displaced in the progress of science itself.

It is not possible to give more than an indication of the important contemporary work on methodology and philosophy of science which is surveyed and systematised in this book. Most students will probably turn first to what is described as a supplement, the essay on "Einstein's Theory of Relativity from the Epistemological Standpoint." The value of this essay is enhanced by the fact that Einstein himself read it in manuscript and gave the author the benefit of his criticisms. It is, Prof. Cassirer tells us, at first sight somewhat strange and paradoxical that such diverse epistemological points of view as those of radical empiricism, positivism, and critical idealism should all have appealed to the theory of relativity in support of their fundamental views. The reason is that they all appeal to experience and they all teach that every exact measurement presupposes universal empirical laws. The real problem is how we reach those laws and what sort of validity we grant them. For positivism they are grounded in sensation and never go beyond its domain; for idealism all equations are results of measurement. We neither measure mere sensations nor do we measure with mere sensations; relations of measurements transcend the given and replace perception with a conceptual symbol. The typical example is the development of modern physics in the theory of relativity.

A quotation better than any description will give an insight into the author's own philosophical point of view:

"Only the idealistic concept of truth overcomes finally the conception which makes knowledge a copying, whether of absolute things or of immediately given 'impressions.' The 'truth' of knowledge changes from a mere pictorial to a pure functional expression. In the history of modern philosophy and logic, this change is first represented in complete clarity by Leibniz, although in his case the new thought appears in the setting of a metaphysical system, in the language of the monadological scheme of the world. Each monad is, with all its contents, a completely enclosed world, which copies or mirrors no outer being but merely includes and governs by its own law the whole of its presentations; but these different individual worlds express, nevertheless, a common universe and a common truth."

H. WILDON CARR.

The Cheyenne Indians.

The Cheyenne Indians: their History and Ways of Life. By G. B. Grinnell. Vol. 1. Pp. ix+35[illegible] 23 plates. Vol. 2. Pp. vii+430+25 plates. (New Haven: Yale University Press; London: Oxford University Press, 1923.) 45*s.* net.

MR. GRINNELL has spent some time each y[illegible] with the Cheyenne Indians ever since 18[illegible] and in this way he has come to know them as [illegible] others can have done. As he says himself:

"I have never been able to regard the Indian a[illegible] mere object for study—a museum specimen. A h[illegible] century spent in rubbing shoulders with them, dur[illegible] which I have had a share in almost every phase [illegible] their old-time life, forbids me to think of th[illegible] except as acquaintances, comrades, and friend[illegible] Yet he can say, "I am constantly impressed [illegible] the number of things about the Indians that I [illegible] not know."

He has embodied the results of his study in t[illegible] large and interesting volumes, which deal with [illegible] aspects of the life of this tribe, and it may come [illegible] a surprise to many to realise how much of the old [illegible] still exists. Mrs. Grinnell and Mrs. J. E. Tuell h[illegible] enriched the book with numerous photographs of [illegible] people, their ceremonies and games, their everyd[illegible] implements and utensils.

The Cheyenne are one of the tribes of the Algonqu[illegible] family; to-day they are divided into the North[illegible] Cheyenne in Montana and the Southern in Oklahor[illegible] and in 1921 they numbered about 3281. They [illegible] themselves Tsistsistas, which probably means "[illegible] people," "those related to us," though the Rev. [illegible] Petter has suggested that it means "cut" or "gashe[illegible] people, from the sign by which they used to design[illegible] themselves. Their movements can be traced back [illegible] about 200 years, but the tales of their origin are, [illegible] G. A. Dorsey also says, rather tales of early migrat[illegible] than of origin. They seem to have come from t[illegible] north-east or east, but from how far north it is i[illegible] possible to discover, possibly from a region north [illegible] the great lakes and toward Hudson Bay, as th[illegible] legends tell of crossing a great lake much in t[illegible] manner of the Israelites under Moses.

The old-time lodges were made of willow sho[illegible] plastered over with clay for the winter, but in summ[illegible] their lodges were woven of peeled and unpeeled will[illegible] stems arranged to make a pattern, and unplaster[illegible] Their present lodges are made of skins, probab[illegible] developed from the wind-breaks of undressed hides [illegible] a framework of poles which they used to set up.

Among methods of self-torture described in t[illegible] chapter on camp customs is one which seems to be[illegible]

certain resemblances to the hook-swinging formerly practised in some parts of India. Dorsey mentions the same form of torture as having been performed in 1903 in connexion with the Sun Dance, but Grinnell says that though it might be done at the time of the Medicine Lodge, it might be done at any time in fulfilment of a vow. Strips of skin were often removed as a sacrifice well-pleasing to the Great Medicine, or Great Spirit, thus leaving scars all over the body.

The Cheyenne are organised into ten groups or divisions, and from the testimony of several of the most aged men, Mr. Grinnell has gathered much evidence of exogamy. Descent was matrilineal, and on marriage a man went to live with his wife's group. If a man deserted his wife, she and her children were cared for by her own group. Each group had its own special ceremonies and taboos, but these old practices have now long passed out of use and cannot easily be reconstructed. So difficult is it that the author says that present-day investigation would lead to the conclusion that tribal descent is in the male line, while up to twenty or twenty-five years ago the old men all agreed that the children belonged to the mother's group. Detailed inquiry into more than fifty marriages of old people, however, resulted in establishing the fact that the man and woman had in all cases belonged to different groups.

The author draws a delightful picture of the home life of the Cheyenne, giving an account of the natural daily round from childhood to death.

The second volume is mainly concerned with the war customs and great ceremonies and dances of the Cheyenne. There are seven soldier bands, mostly named after some animal; but not every strong and able-bodied man is necessarily a member of one of these bands. These bands form a kind of standing army and enforce the commands of the chiefs. To each band belonged four young women, chosen from the best families in the camp. Their duty was to be present at the meetings of the band, to take part in the singing and dancing, and sometimes to do the cooking. It was an honourable position; but though it was looked on as a kind of profession, no girl was obliged to remain in the band against her will; she generally resigned on marriage, though sometimes a married woman was chosen. There was also a curious institution called Contraries, usually two or three Contraries in each tribe, who acted and spoke in the reverse or opposite way to that of common usage. They had serious duties to perform, and might not mix on equal or familiar terms with the rest of the tribe; each had to "walk by himself," lest those treading in his tracks should meet with evil results. One of the chief duties of a Contrary seems to have been to protect his tribe from thunder, and to do this he carried a peculiar form of bow called a thunder-bow. He could only be relieved of office if some one asked for his bow, or if he lost it by any accidental means.

There is also a Contrary Society, the members of which, though they seem to have no connexion with the Contrary warrior with the thunder-bow, also act by contraries and are in some way connected with thunder. The members are mostly old men and women, and appear to be buffoons, but at the same time they are believed to be able to help the sick. In the Massaum Ceremony (Crazy or Animal Dance), which is fully described, the Contrary Society plays the part of the hunters who pretend to kill the animals represented by other actors in the ceremony. This Massaum Ceremony is an ancient rite and seems originally to have been performed in order to increase the supply of food in the camps. It takes place when any man makes a vow to perform it in order to obtain some benefit for himself, but at the same time it benefits all the community. It lasts for five days.

A detailed account is also given of the Medicine Lodge, the midsummer or summer ceremony of many Plains Indians, which was fully described by G. A. Dorsey in 1905 in the Field Columbian Museum Publication 99, as a part of his studies on the Sun Dance of the various tribes. This term, however, comes from the Sioux, and refers to one part only of the Cheyenne ceremony, which now lasts three, but formerly eight, days. This ceremony, too, is offered as a sacrifice by one or more members of the community. It was at this ceremony that the self-torture often took place.

Though the Indians are repeatedly said to be very religious, there seems to be no official priesthood; but for these great ceremonies there are special "instructors," who take the part of priests or masters of ceremonies.

As may be seen from this résumé of some of the contents, the book is full of interest, and it is written in a simple straightforward style which makes the reader feel all the time that the subject is dealt with by one who is intimately acquainted with the matter in hand. It is a most valuable and sympathetic study of a people whose old customs are still in a measure retained, though obviously breaking down under modern conditions, and thus it is well to have these things recorded before more is forgotten. As it is, the author is frequently obliged to confess that in some cases the meaning of certain ceremonies appears to have been lost.

Wood-fibres of some Australian Timbers: Investigated in reference to their Prospective Value for Paper-pulp Production. By Richard T. Baker and Henry G. Smith. Pp. 159. (Sydney: Alfred J. Kent, 1924.) n.p.

DURING the War the Australian people suffered much inconvenience from the deficient supply and high price of paper and paper-making materials, which could be procured only by importation from Europe and North America. This directed attention to the possibilities of the manufacture of wood-pulp at a cheap rate in the Australian forests; and during recent years some investigations have been carried out by the different governments of the Commonwealth. A short account of the nature and results of these inquiries is given in the introductory part of this book; and it is apparent that there is no lack of suitable kinds of timber. Sites for pulp mills can be found in certain forest districts where an abundance of pure water is available, an essential requirement for commercial success.

The main part of the work is devoted to a detailed study of sixty species of trees, as regards both the microscopic structure of the wood-fibres and the bleaching and felting properties of the separated fibrous material. Each description is accompanied by a photomicrographic illustration. Most of the species of Eucalyptus are of little value for paper-making owing to the shortness of their fibres; but the so-called "ashes," which constitute one section of this large genus, have long and flexible fibres, and are considered to be very promising for the production of "chemical" wood-pulp. The only conifer studied, *Araucaria Cunninghamii*, is suitable for the same purpose, and "sulphate" pulp is manufactured from it on a commercial scale at Yarraman Creek in Queensland.

The Control of the Speed and Power Factor of Induction Motors. By Dr. Miles Walker. Pp. 151. (London: Ernest Benn, Ltd., 1924.) 18*s*. 6*d*. net.

IN recent years the use of the three-phase system of distributing electric power has been rapidly extending. The great advances made in the methods of controlling economically the speed of induction motors are not known to many engineers. It is necessary, in order that they may choose the best kinds of motor for their every-day work both from the points of view of ease of control and of economy, that they should be able to study for themselves their relative advantages and disadvantages. We therefore welcome this book by one of the leading authorities on the subject.

In Chapter i. the author gives a sketch of the fundamental theory. He lays stress on the importance of the mathematical method of inversion as this leads to a simple method of proving the "circle" diagram. We are sorry that no proof is given of the geometrical theorems of inversion, as students may have difficulty in proving these for themselves.

A very full description is given of the methods of controlling the speed of an induction motor. In battleships two speeds are desired, one for cruising and one for "fighting." In the latter case the highest attainable speed is wanted. The fighting speed is usually about 50 per cent. greater than the cruising speed and requires about 3·5 times as much power. In the United States, where many ships have been fitted for electric propulsion, the method of pole changing is the one generally adopted. In the later chapters of the book, brief descriptions are given of the cascade motor and the frequency converter. A good description is given of the phase advancer designed by Gisbert Kapp.

Silent Highways of the Jungle: being the Adventures of an Explorer in the Andes and along the Upper Reaches of the Amazon. By G. M. Dyott. Second edition. Pp. 320 + 16 plates. (London: Chapman and Dodd, Ltd., 1924.) 7*s*. 6*d*. net.

THE interest of this book is more adventurous than scientific, but it is most readable and the pages are seldom dull. The author was commissioned by the Peruvian Government to investigate the possibility of aerial routes between the Pacific littoral and that isolated part of Peru which lies around the head streams of the Amazon. With this end in view, he made a journey overland from the port of Pacasmayo through the Andes by Cajamarca and Moyobamba to Yurimaguas and down the Huallaga and Marañon to Iquitos. This was a relatively easy task: the return by a more northern and partly unknown route was difficult. In the forests of the upper Marañon, Mr. Dyott was basely deserted by his carriers and left to his own resources in a trackless wilderness. At his last gasp he fell in with forest Indians, by whom he was held a virtual prisoner for some weeks before he got away and returned to the coast. The book describes vividly the conditions of travel in those remote regions, and has a good deal of information about rubber and agricultural possibilities, but its chief value lies in the account of the Aguavuna Indians. Existing maps were found to be faulty, but Mr. Dyott had no means of making new ones.

Physiotherapy Technic: a Manual of Applied Physics. By Dr. C. M. Sampson. Pp. 443. (London: H. Kimpton, 1923.) 30*s*. net.

MAJOR SAMPSON defines physiotherapy as "the use of physical remedies in the treatment of disease or disability," and classifies these remedies as thermal, chemical, mechanical, and electronic. Of the value of such methods of treatment there can be no doubt, but the author of "Physiotherapy Technic" has certainly not justified his claim that physiotherapy is destined to be the salvation of therapy. The main defect in this book is the very loose style of thinking and construction which it indicates. For the description of one technique we are referred to "Treatment of Optic Neuritis," but have failed to find the reference. The statement that "things not equal to the same thing are not equal to each other" is absurd, but its appearance as an argument in a scientific text-book is worse than absurd.

Major Sampson's experience entitles him to speak with authority on the methods of application of physical remedies, but the scientific reader will probably tire of the effort to discover what these methods are.

Letters to the Editor.

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.*]

Sex Change and Breeding in the Native Oyster, *O. edulis*.

IN NATURE in 1922 (vol. 110, p. 212) it was shown that when an oyster spawns as a female it changes immediately into a male. In a later number of NATURE (vol. 110, p. 420) Spärck, who had been working on similar lines to the present writer, was able to confirm this observation. I have since continued similar observations on a large number of oysters with the same result, so that it can now be definitely stated as a fact that the female-functioning oyster normally changes into a male at about the period of the extrusion of ova; and further that the rapidity of the change strongly suggests the existence of a substance—which causes this change—in a fluid circulating in the body.

In the same number of NATURE I stated that experiments had been started to investigate the conditions of the reverse sex-change, that is, from male to female in both young and old oysters. The occurrence of this change has been suspected to occur on general grounds, but, so far as is known, has not been demonstrated. A brief summary of the results can now be given. In the summer of 1922, 115 oysters, which were proved to be male on a certain date by microscopic examination after boring a hole in the shell, were isolated in a cage in the sea along with 78 identified females. This experiment was a failure owing to an accumulation of mud in the experimental cage, and was repeated in July 1923 with 101 freshly determined males, and 28 fresh females, along with the remainder of the oysters the sex of which was known in 1922. By October 1923 nearly all the oysters had recovered, and most of them had put on good growth, but a sample of 18 oysters, which were male in July, were proved after a thorough examination to be either mostly feebly male or neuter sex. None of the oysters were in spawn at this time.

In June and July this year the oysters were again examined, with the following result at the instant of examination: of the 6 remaining individuals which were male in 1922, 50 per cent. had changed to females, and two of these were carrying recently extruded embryos; of the 69 remaining individuals proved to be male in 1923, only two extruded embryos at the time of examination; the rest are being kept intact in the sea to permit periodical examination for later spawning females.

Besides these proved male oysters, others which have spawned as females—which, as has now been established, would have changed immediately afterwards into males—have been also kept isolated in compartments of a cage in the sea. Of 16 remaining individuals female in 1922—and therefore by inference afterwards immediately male — 5 were female in July 1924, and 1 was carrying embryos at the time of examination; similarly, of 20 oysters female in 1923, and immediately afterwards male, 6 had changed into females in July 1924, and of these 2 were carrying embryos at the instant of examination.

The experiments described above were carried out at West Mersea on the East Coast, but similar results have also been obtained on the River Yealm on the South Coast. In the Yealm experiment some interesting cases occurred; for example, an oyster male in July 1922 was examined on July 9, 1923, and found to be still male, but nearly seven weeks later, on August 31, this same oyster was carrying an enormous number of fully developed shelled larvæ, and a few days later, on September 4, was rapidly developing sperm. This is an extremely interesting and important result, both theoretically and economically. In the same cage were 18 oysters, which were obtained from different parts of England; these had spawned as females in 1923, and afterwards changed immediately to males; of this group, 3 extruded numerous embryos in June to July this year, and were found by microscopic examination to have changed back again to males at once. It is expected that some of the remainder will have embryos during the next few months. Thus already 11 per cent. of these oysters have had at least *four experiences of sex in about a year*, reckoning from July to July, and this is believed to be the normal sequence of events in the European oyster for a good proportion of individuals which assume female characters in spring or early summer. It is, however, still an unsolved problem what proportion of individuals which are male in the spring change during the summer into females. So far I have only obtained one such case, but the reason would appear to be found in the difficulties of the work. It has been shown elsewhere that too much handling of oysters in summer causes "bleeding," and a loss of condition (Orton, "Fishery Investigations," vi. 3, 1923 (1924)), so that it is necessary to work continuously on or in close proximity to good oyster beds to obtain good results. Efforts are now being made to fulfil these conditions in further work.

In all the observations recorded above, it is to be noted that sex-conditions are only determined at the instant of examination, and as it is clear that sex-change does occur very rapidly, some sex-changes may have been missed. It is believed that in many cases changes of sex have been missed.

In the breeding of the oyster there are phenomena of a confusing nature which can only be referred to briefly here. It has been found that the mere dredging of oysters in the breeding season will cause those females which are ripe to spawn. I have called this phenomenon "forced spawning," and it has some peculiar results. The spawning female may extrude the whole or indeed any proportion of its ova. Now there are good reasons for believing that the act of spawning initiates the internal changes which result in changing the sex to male, and undoubtedly the sex-change does occur in females which have undergone forced spawning without expelling all their eggs. As a result the gonad in such cases would appear to the uninitiated to be hermaphrodite. Such individuals are, however, physiological males, and it has been shown elsewhere (*loc. cit.*) that the "residual" ova, as they have been termed, are absorbed, or dealt with in other ways. There is nevertheless a small proportion of hermaphrodite oysters which cannot be explained satisfactorily as physiological males, and since the act of spawning as a female may cause or is closely associated with the causes of the change to maleness, it is possible that stimuli, other than spawning, may produce a like result in a ripening female, and so produce a true hermaphrodite gonad.

Other explanations are, of course, possible; but the *proximal* cause of the change from male to female is still to be found. The change to female occurs commonly in the winter or early afterwards, but we have seen that it does also occur in the summer, though to an unknown extent; it is therefore apparently independent of seasonal conditions. An explanation which would satisfy those conditions would appear

to be as follows: at the birth of an oyster the conditions which determine sex result at first in the establishment of a functional male gonad (this statement is apparently true, but must not yet be regarded as having been definitely proved); at some time later, generally at the end of the winter or even during the summer, the predominance of internal male-determining conditions is lost, and female characters are assumed. At this stage the position is clear, for immediately the female character is lost, namely at spawning, the sex potentiality swings back to predominant maleness. It has been seen that the male condition can occur twice in one summer, but we have no evidence yet of the occurrence of femaleness twice in one summer.

Even if we assume that specific hormones are responsible in predominance for the condition of maleness and femaleness respectively, yet it would appear that some factor connected with external conditions is the cause for the assumption of femaleness. Can this be merely the accumulation of reserve products in a quantity sufficient to produce a crop of ova reacting on the general system of the organism after the male-determining mechanism, so to say, has run down? This condition might be an excess of glycogen in the body over that amount which can be stored, for example. A fact which lends some support to this view is that starved oysters are either feebly male or of neither sex. It is at this point that the study of sex-change appears to touch the all-important problem—for oyster-culture—of the "fishing-up" or natural fattening of oysters, on which subject there is still a great deal of work to be done. The investigations have been made partly by means of a grant from the Royal Society, and will be described in full on completion of the work in the Journal of the Marine Biological Association.

Relation between Pressure Shift, Temperature Class, and Spectral Terms.

IN a letter to NATURE of June 21, p. 889, I have shown the existence of a numerical relation between the pressure displacements of the lines of the iron spectrum, the temperature class of the lines, and the magnitude of the spectral terms which originate those lines by combination. It now seems probable that this relation is not only valid for iron, but may be a more general relation. Unfortunately, the available measures of temperature and pressure effects are neither very numerous nor very extensive, so that the general validity of the relation cannot at present be fully demonstrated. In a few cases, however, the available measures suffice to show that the relation holds very accurately.

The most complete data at present available are those for titanium. King (*Astroph. J.*, 39, 145, 1914, and 59, 1924) has studied the temperature effect; different authors have investigated the displacements by pressure, the results of Gale and Adams being the most extensive (*Astroph. J.*, 35, 1, 1912); C. C. Kiess and H. K. Kiess (Journ. Opt. Soc. Amer., 8, 607, 1924) have studied the structure of the spectrum of the neutral atom, and given the absolute values of the terms which form a great number of multiplets (quintets and triplets). Following the plan adopted for iron, the mean values of pressure shifts (taken from Gale and Adams) for multiplets of titanium have been plotted in Fig. 1 against the mean values of the sum of the terms forming each multiplet. The curve thus obtained is quite regular, and similar to that for iron, so that the two may be approximately superposed by a simple translation. Unfortunately, it is only possible to follow the curve for titanium up to displacement 0·20 cm.$^{-1}$; those lines which have appropriate terms to give displacements between 0·20 and 0·50 cm.$^{-1}$ are out of the range observed. In the tables of Gale and Adams there are some lines which show displacements greater than 0·50 cm.$^{-1}$, but they are not classified in multiplets.

Very recently, Laporte (*Zeit. für Phys.*, 23, 135, 1924) has made an estimate of the absolute values of the iron terms, giving 48,000 cm.$^{-1}$ for the term A, to which, in my first letter, the arbitrary value 60,000 cm.$^{-1}$ was assigned. In a future communication it will be shown that this value is a little too small. If the value 50,000 cm.$^{-1}$ be adopted, all the values of the remaining iron terms must be lowered by 10,000 cm.$^{-1}$, and the sum of two terms by 20,000 cm.$^{-1}$. When this correction is applied, the titanium curve superposes on the iron curve very closely, thus indicating that the relation for iron is not only of the same form for titanium, but also of the same order of magnitude.

The curves for iron and titanium show that the classification of lines in Classes I, II, . . ., may be

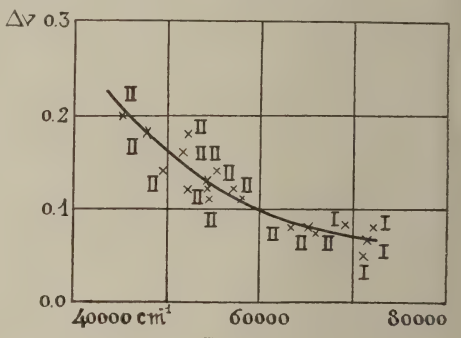

FIG. 1.

only a first approximation; the effect of temperature, like that of pressure, may be a continuous function of the sum of the terms. King remarks (*Astroph. J.*, 37, 264, 1913): "An examination of Table I. (referring to the classification of iron lines) shows a considerable variety as to the rate of growth among lines placed in the same class." In order to prove that the effect of temperature is as indicated by the curves for titanium and iron, I have examined in some detail all the spectra which have been investigated for multiplets and for temperature effects. In all cases the assumption has been quite confirmed. The details will be given elsewhere, but meanwhile the following examples will illustrate this point.

In the neutral iron spectrum there are several multiplets of Class I. If we arrange them in a list beginning with the multiplet for which the sum of its terms has the greatest value, and ending with that for which the sum has the smallest value, it will be noticed that we have at the same time arranged the multiplets beginning with the most sensitive at low temperature, and ending with the less sensitive. The greatest value for the sum of the terms is given in iron by the intercombination multiplet AE, of $n^5{}_3 - n^7{}_3$ (incompletely given by Walters, but now completed) in Paschen's notation, formed by the most sensitive lines of the iron temperature classification λλ5110, 5166, 5169, 5204, 5225, 5247, 5250, 5255; these lines, however, do not appear in King's furnace at 1400° because the sensitiveness of the film used was very poor beyond the blue. The relation of intensity of this multiplet AE in the arc and in the

rnace at low temperature is 1/1·2 ; multiplet AH, hich is situated in the middle part of the list of ass I multiplets, gives 1/1 for this relation, and ultiplet AJ, which is near the end of the list, gives o·2. So the sensitiveness of the multiplets at low mperature decreases gradually when the sum of he terms decreases.

It is interesting finally to remark that the iron tercombination multiplets AE, AZ, AX do not ppear reversed in spite of their being the most nsitive groups of this spectrum and combinations the ground level A. I think that it is not a rticularity of the iron spectrum, but a general ature of all intercombination lines. The resonance nes of magnesium, calcium, strontium, barium, and anganese, which are also intercombinations, are not und reversed. The titanium resonance lines, which ay be those of the intercombination multiplet $^4_4 - n^5_3$ (λλ5397, 5409, 5426, 5447, 5461), because ey give the greatest value for the sum of the terms this spectrum, are also found to be very sensitive, t not reversed.

The Use of Naphthalene as a Fumigant in the Control of Red Spider and other Pests in Cucumber Houses.

A LETTER on "The Effect of Naphthalene Vapour n Red Spider Mite," signed by Mr. O. Owen and yself, appeared on pp. 280 and 281 (No. 2849, ol. 113) of NATURE on June 7.

Since that letter appeared, experiments have been rried out in distributing naphthalene in various ates of division over the beds in cucumber houses. he state of division was determined simply by assing pure commercial white flake naphthalene rough a graded series of sieves, ranging from 4 20 meshes to the inch ; "milled" naphthalene as also been used.

With naphthalene which has been passed through sieve of 16 meshes to the inch (=256 meshes to ne square inch) all stages of the red spider mite *Tetranychus telarius* L.), including the eggs, were illed in cucumber houses within a period of 24 ours, when the soil surface was at or above a emperature of 24° C. The amount of naphthalene sed was 3 lb. to every 100 feet of bed. Similar esults could only be obtained with naphthalene assed through a sieve of 8 meshes to the inch by sing double the weight of naphthalene, while owdered or milled naphthalene did not kill all the ider, and tended to produce scorching of the lants.

Experiments have shown that very finely divided aphthalene volatilises too quickly, and that the rge concentration of vapour resulting does not emain long enough in the atmosphere to kill all the ites. With milled naphthalene, on the other hand, he particles adhere so closely together that neither uitable distribution nor an adequate concentration f the vapours are obtainable.

When pure commercial white flake naphthalene as passed through a sieve of 16 meshes to the inch, nd broadcasted by hand at the rate of 3 lb. to every oo feet of border, no scorching of leaves or damage o plants resulted, provided that the plants were well atered before, and the atmosphere kept moist uring fumigation. Plants lacking water, however, ere often considerably scorched though not per-anently injured.

During fumigation the fruit is liable to taste slightly f naphthalene, so that it is inadvisable to cut fruit until the odour of naphthalene has disappeared from houses treated. If exposed to fresh air, the taste soon leaves the cucumbers.

Other pests liable to destruction by naphthalene fumigation in cucumber houses are wood-lice (species of Porcellio, and Armadillidium) and crickets. The fumigation has now been carried out on the commercial scale for cucumbers, and has proved effective in houses and blocks of houses ranging from 50 to 200 feet in length, and from 8 to 20 feet in height. It was found unnecessary to increase the amount of naphthalene in the higher houses.

In all cases the red spider mite has been killed without damage to the plants, by one fumigation, and a large proportion of the wood-lice have at any rate been destroyed.

Oscillations in Vacuum Tube Discharges.

A LETTER from Profs. Karl T. Compton and Carl H. Eckhart appears in NATURE of July 12, in which reference is made to experiments on oscillations occurring in vacuum tube discharges functioning with the aid of a hot cathode.

I should like to be allowed to point out that, so far as I am aware, the first published notice of this effect was a paper of mine in the *Radio Review* (now the *Wireless World and Radio Review*) of November 1919.

The general explanation there offered of the phenomenon requires some modification, but it was clearly shown that in the particular case of mercury vapour, ionic oscillations of easily regulated frequency could be produced by merely altering the potential conditions of the tube.

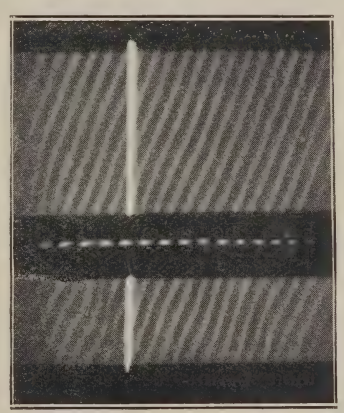

FIG. 1.

May I add that during the past year I have been following up these results in the particular case of vacuum tube discharges both with hot and cold cathodes with interesting results ? When the discharge obtained from a battery of accumulators is viewed in a rotating mirror, cases are found when the appearance presented by the photograph (Fig. 1) is the rule. (See Aston and Kikuchi, Proc. Roy. Soc., 1921.)

The inclined lines represent flashes of luminosity proceeding at a constant velocity away from the cathode, apparently moving at a rate which depends both on the gas pressure and on the applied potential.

The spectrum when examined by the Fabry and Perot étalon method does not exhibit, however, the Doppler effect.

These and other results will be presented and discussed in a paper now in course of preparation.

Absorption Spectra of Some Metallic Vapours.

In the course of our experiments on the absorption of light by vapours of different metals, we have recently photographed the absorption spectra of lead, bismuth, antimony, thallium, and magnesium with the following results :

(1) The absorption spectrum of lead shows at 1100° C., besides the fundamental line 2833 and some other lines, a faint banded spectrum which has not been described previously. These bands extend from λ3000 to λ3320 Å.U. The interval between the various bands is nearly constant and is equal to 32 Å.U.

(2) The absorption spectrum of bismuth shows besides the "raie ultime" 3067, a typical banded spectrum containing about twenty bands. The absorption at each of these bands is very diffuse and complex, consisting of a number of fine bands. With increase of vapour density all the bands gradually fuse together (beginning from the short wave-length side) to form a region of continuous absorption.

(3) The absorption spectrum of antimony shows a fine line and a banded spectrum on the short wave-length side of this line, which has not been described previously. The fine line is at λ2310, and the bands extend from λ2304 to λ2200, with a constant interval of 15 Å.U. nearly. Eight of these bands have been photographed.

(4) A long column of non-luminous vapour of magnesium is found to absorb, besides the line 2852, λ4571, the single line spectrum of the element.

(5) The absorption spectrum of the non-luminous vapour of thallium shows at high temperatures, besides the lines of sharp and diffuse series, some prominent bands and lines due probably to Tl_2 molecules. A study of anomalous dispersion of the vapour by the method of Kundt's crossed prisms showed that at λ3775 there is anomalous dispersion and that at 5350·6 the phenomenon is much weaker.

A detailed account of these experiments together with the photographs of the absorption spectra will be published shortly.

The Theory of Hearing.

To the letters of Sir R. A. S. Paget and Mr. Wilkinson in Nature of July 19 I will reply in regard to the piano experiment by saying that what a person hears is chiefly what he expects to hear. A conspicuous example is that of hearing the tones in whispered vowels. Every observer hears a different system. In the piano experiment I can hear fairly good vowels for *ah* and *oo* when sung ; otherwise the result is vague. Yet in speech I hear every minute shading. I am quite in agreement with these gentlemen and most other writers in believing that the vowels are characterised by tones of definite pitch, but that is a matter that cannot be established by any such method.

The portamento piano experiment, however, furnishes a definite proof that the ear is not a resonating organ. When a tone is sung into the piano portamento *all* the strings vibrate more or less, and the result is a complete jangle. Exactly the same result would occur if the ear were a resonating organ. Much singing and *all* speech is portamento. If the basilar membrane acted by resonance, the voice of the singer would usually be a jangle with no pitch, and for the melody of speech we would have only a confused noise. This is exactly what I pointed out in my original letter to Nature, April 22, 1922. The piano as a resonating organ responds to portamento singing by a perfect jangle. That the ear responds by a sensation of a clear rising or falling tone is a quite adequate proof that it does not possess a resonating organ. This ought to settle the matter for good from the physical point of view. To those of us who are accustomed to work with delicate human tissues the Helmholtz resonance theory is simply unthinkable.

The resonance theory is dead and there is no use in wasting time in trying to put life into it again. The deformation theory, as explained in Nature for April 26, rests on distinct theses in strict accordance with anatomical and physiological facts, not one of which has been called in question.

Germanium and its Derivatives.

Until recently, germanium was regarded as one of the rarest of metals, but recent discoveries of larger sources of its minerals lend interest to any possible applications of this element. Germanium dioxide is appreciably soluble in water and an aqueous solution of a concentration of one in 5000 has a marked inhibitory action on the growth of *Bacillus coli communis*.

So far little is known concerning the organic derivatives of germanium which we are now investigating (Chem. Soc. Trans., 1924, 125, 1261). With the aid of the Grignard reaction, germanium halides have furnished germanium tetraphenyl, germanium triphenyl bromide and oxide, and hexaphenyldigermane. Water-soluble organic derivatives of germanium have also been obtained which are now under examination in this laboratory.

Mathematics at British Universities.

A little time ago I turned light-heartedly to the study of relativity. I had no doubt of the sufficiency of my equipment for such study because two British universities had found me worthy of a degree in mathematics. You can imagine my surprise when I found how little connexion the mathematics of relativity had with my university studies, and what a serious study of new subjects I must undertake. Chief among the new subjects is vector analysis or tensor calculus, and I am puzzled that so many continental writers (as well as a few in this country) show a command of vector analysis, while my two universities knew nothing of it.

It is, however, some years since I left these universities, and it may be that vector analysis has now attained an appropriate position there. It is on this point that I hope your readers may help me by telling me which universities include vector analysis in their courses, and by indicating how far they go in this and other subjects preparatory to relativity. In this inquiry I am not actuated by mere curiosity. I am anxious to know, and I am sure many of your readers also wish to know, whether the teaching of mathematics in our universities is abreast of the times. I hope, therefore, that some one at Cambridge will say what is being done there, or if Cambridge is doing nothing, I hope some one elsewhere will be able to show that his university is making good the omission of Cambridge.

A Beginner in Relativity.

Surveys from the Air: the Present Position.[1]

THE issue by the War Office of the first Report of the Air Survey Committee affords an opportunity of reviewing the progress made in this method of making maps; more especially because the excellent report in question puts together, in a comparatively small book, a mass of information not easily accessible elsewhere, and is written by the authority of the War Office, the Air Ministry, and the Ordnance Survey.

In discussing the matter it is very desirable to bear in mind that the object in view is the construction of an *accurate* map. It is this factor of accuracy which creates most of the difficulties found in practice. Indeed, if we are content with a pictorial representation of the ground, or with a sketch of uncertain trustworthiness, there is no problem—the thing is already done. It is when we try to produce, by this method, a map of the same high degree of correctness that we expect from modern ground survey that we find that there are many obstacles to be overcome.

Owing to the special conditions that obtained on the Western Front during the War, the difficulties of the method were very commonly underrated. In this area there were available the old cadastral plans of France, discontinuous and some eighty years out-of-date, but still showing correctly the features which survived. The problem in this case was to correct an out-of-date map of which there existed a trigonometrical frame work. Moreover, along the British portion of the line the ground was generally flat, or only gently undulating, a circumstance which made the conversion of an air-photograph into a plan much easier than it would otherwise have been. The Committee reports that "an undue optimism as to the ease, cost, and suitability of air photo-topography was common at the close of the War."

Broadly speaking, we may tackle the problem in two ways. Either we may take the photograph of the ground without any special precautions as to the axis of the camera being vertical, and without attempting to ascertain its height above the ground. We must then, in the ordinary case, rely upon a fairly close network of measured points on the ground, and from the positions of their representations on the photograph we can, in several ways, determine the tilt, and direction of tilt, of the camera, and its height at the moment of exposure; or we may take precautions to fly level and straight at a known height.

The latter system has been carefully studied at Cambridge by Prof. Melvill Jones; and it is to him and to Major J. C. Griffiths that we owe its present development. It appears that "when the pilot is flying in air weather at a height sufficient to escape surface air pockets, the probable errors of tilt and difference of flying height have been reduced to 1° and 40 ft. respectively." Truly remarkable results. When it is considered that during the War the average tilt was of the order of 10°, it will be seen what excellent progress has been accomplished in this direction. But still, straight and level flying only solves the difficulties in special cases. When there are considerable differences of level in the terrain photographed, large errors will appear on the resulting map. Where any approach to accuracy is desired, the system of making a map from an uncorrected "mosaic" of photographs taken in this way can be applied only to level areas. But probably it can be effectively applied to the surveys of estuaries and deltas and perhaps to the mapping of large native towns, which in most cases are scarcely worth accurate large-scale ground surveys. Sometimes in war the use of uncorrected mosaics may be inevitable; but that is scarcely the question before us.

In the general case, what is required is the means of mapping hilly and undulating country at a cost which will compare favourably with that of modern ground surveys. It may be as well to state at once that this state of affairs has not nearly been reached. It looks, in fact, as if it would be a long time yet before it is reached. Much patient work is still necessary, though it is only fair to say that much has been done. Experimenters are feeling their way, and are as yet unable to decide which of many promising paths is most likely to lead to the desired goal.

Apart from the use of uncorrected "mosaics" there are two principal problems to be solved. The first is to map, by means of air-photographs, a hilly district which has been so well provided with a framework of fixed points that, in general, four of these, well distributed, will be found on each photograph. The second problem is how to survey with accuracy, from air-photographs, a limited region or gap between two surveyed areas, the region in question not being provided with any fixed points. It is not to be assumed in either problem that it is possible to arrange for the axis of the camera to be vertical; and in each problem we must take account of the hilly character of the ground, and attempt to contour it.

It may be taken for granted that the focal length of the lens is known and also the position of the optical centre of the plate. Now if, in addition, we could find the amount of the tilt and the direction of the tilt, the problem would be much simplified. The Committee, therefore, turned its attention to the determination of the tilt by means of a gyroscopic apparatus, and it is reported that during approximately straight flight the apparatus worked well and that an accuracy of one-quarter of a degree might be expected.

An alternative method of finding the tilt is to make use of a "tilt-finder," a machine devised by Major MacLeod, which reproduces, in miniature, the conditions which obtained in the field (Fig. 1). To use this machine it is necessary to know the focal length and optical centre, and to have available the positions of three ground points, which in the latest model need not be of the same height. Three planes are dealt with: namely, the ground plane P′, which need not be horizontal; the map-plane M, which must be horizontal; and the photo-plane P, of which it is desired to ascertain the tilt. By a succession of approximations it is possible to determine the tilt with a satisfactory degree of accuracy.

If the terrain to be surveyed is flat, or nearly so, and if four points of which the co-ordinates are known are shown on the photograph, then it is possible to cover the map with a rectilinear grid, and by a graphic construction to draw the representation of this grid on

[1] Report of the Air Survey Committee. No. 1, 1923. Pp. 131. (London: H.M. Stationery Office, n.d.) 4*s.* 6*d.* net.

the photograph (Figs. 2 and 3). The photo-grid will be composed of two sets of straight but converging lines. If the grid is close enough, the detail can be drawn in on the map without difficulty.

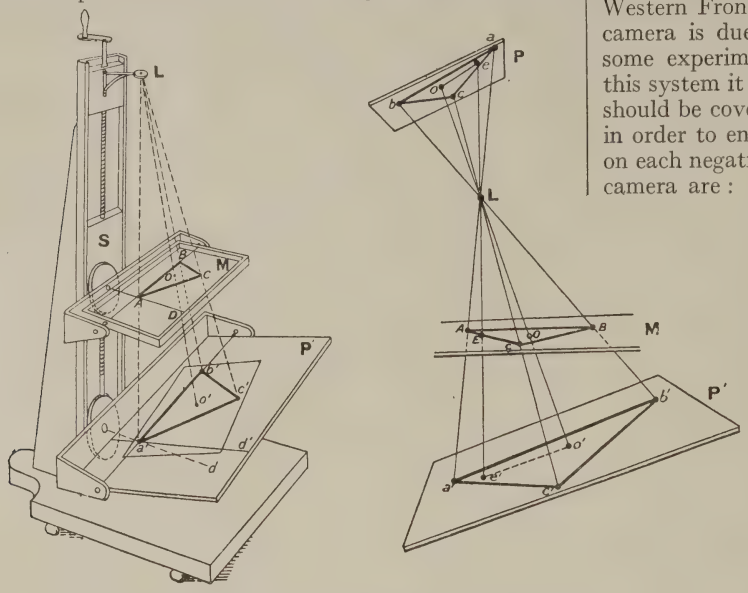

FIG. 1.—The tilt-finder (Mark I). Reproduced by permission of the Controller of H.M. Stationery Office, from the Report of the Air Survey Committee, No. 1, 1923.

The problem is, of course, capable of mathematical treatment. If there are given the focal length and at least three known points, it is possible to determine the position of the camera in the air and the constants of the plate. Where the ground is approximately level the mathematical treatment is easy; but in hilly country it becomes cumbrous — and expensive.

In hilly country, for the purpose of plotting the relief, it is useful to employ oblique photographs, in addition to those taken with the plates horizontal. If the "obliques" are taken at lower altitudes than the horizontal plates, they can be at high tilts and are then most valuable. This may involve, however, the uneconomical procedure of double flights. Generally, the more the plate is tilted the more valuable it is for determining the relief and the less valuable for planimetry.

The rectification of the air-photograph can also be accomplished photographically. This method was, in fact, in use by the British and French armies on the Western Front. An up-to-date form of the rectifying camera is due to M. Roussilhe, who has undertaken some experiments for speed, cost, and accuracy. In this system it is necessary that the area to be surveyed should be covered with a close network of fixed points in order to ensure that three fixed points shall appear on each negative. The essential parts of the rectifying camera are: a projecting lantern, a negative-carrier, a lens-carrier, and a screen-carrier. The carriers are all capable of horizontal movement and of rotation. A tracing or diagram of the three control points, plotted to scale, is fixed to the screen-carrier, and the apparatus is manipulated until the projected images of the three control points in the negative correspond with the three points on the screen-carrier. If the three points are not all in the plane of reference a second adjustment will be necessary. The adjustment having been made, the tilt can be found to within ½ degree, the position of the map plumb-point to within 10 metres, and the height to within 10 metres; the rectified print is the required map, to scale. M. Roussilhe has shown that, provided that the differences in level of the ground to be surveyed do not exceed 100 metres, and the scale of the photograph is not larger than 1 : 5000, the distortion due to relief may be neglected. The method is a promising one, especially for flat or undulating country. The time required for the whole operation for one plate is stated to have been reduced to twenty-five minutes.

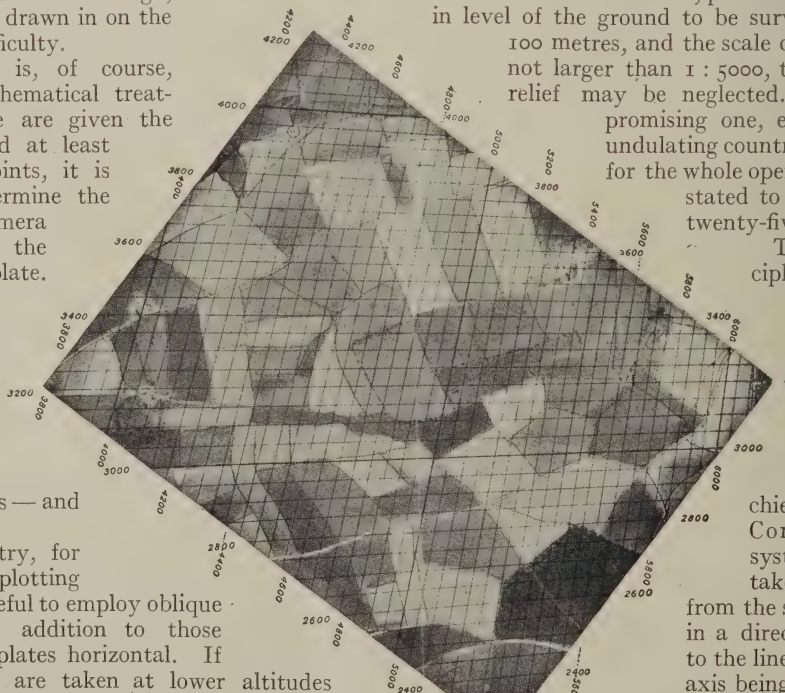

FIG. 2.—The photo-grid. Reproduced, by permission of the Controller of H.M. Stationery Office, from the Report of the Air Survey Committee, No. 1, 1923.

The stereoscopic principle has also been applied to air photo-surveying, and may be exemplified by the system evolved by Prof. Hugershoff, which is that chiefly dealt with by the Committee. In this system, photographs are taken in pairs, by hand, from the side of the aeroplane, in a direction at right angles to the line of flight, the optical axis being tilted to about 60°. Each photograph must include three fixed points; and from the positions of these points on the photograph the position of the camera in space is measured, and the direction of the optical axis. Each pair of photographs is then placed in the autocartograph, which is, in principle, much the same as the stereoautograph

Von Orel. By means of the autocartograph the map can be plotted mechanically; and by clamping the height lever at a particular height, and keeping the stereoscopic pointer (in appearance) just in contact with the ground, a contour can be traced. The whole apparatus is elaborate and expensive, and it would need many pages to describe it at all adequately. It has possibly come to stay, though it has not yet been subjected to exhaustive tests. The stereoscopic method has the great advantage that it is possible by its means to draw the contours of a bare hillside, an impossibility with any point-by-point system; and this requirement of drawing contours must be met if air photo-surveying is to have any general application to topography. A topographical map of the normal type shows the ground features by approximate contours, which are controlled by a trigonometrical framework. At present, apart from the stereoscopic methods above mentioned, air photo-surveying is incapable of supplying the contours in open country. It is therefore, at present, only fitted for the survey of flat countries. It would be waste of time and money to prepare a ground plan by air methods and then go over the same ground again for the survey of the contours.

The position that has been reached briefly this: Air photo-surveying is indispensable in war. In peace-time it has a unique field of usefulness for archæological purposes; for it has been shown by Colonel Peazeley, Mr. O. G. S. Crawford, and others, that air photographs may show ancient features that are invisible except from the air. For surveying purposes air photographs are probably, even now, of value for the mapping of estuaries and deltas, and possibly for the mapping of native towns on medium scales. It also appears likely that in flat or very gently undulating country the method can be used for the construction of cadastral plans without contours, with satisfactory speed and accuracy; and that in such circumstances the cost may be brought down to a practicable figure.

But at present, for the construction of contoured topographical maps, air photographs cannot be economically employed; and the same remark applies to the construction of maps and plans, on all scales, for all purposes, in hilly country. The future use of air photographs, so far as concerns the general peace-time application of the method to the construction of accurate topographical maps, would appear to lie in the development of stereoscopic methods.

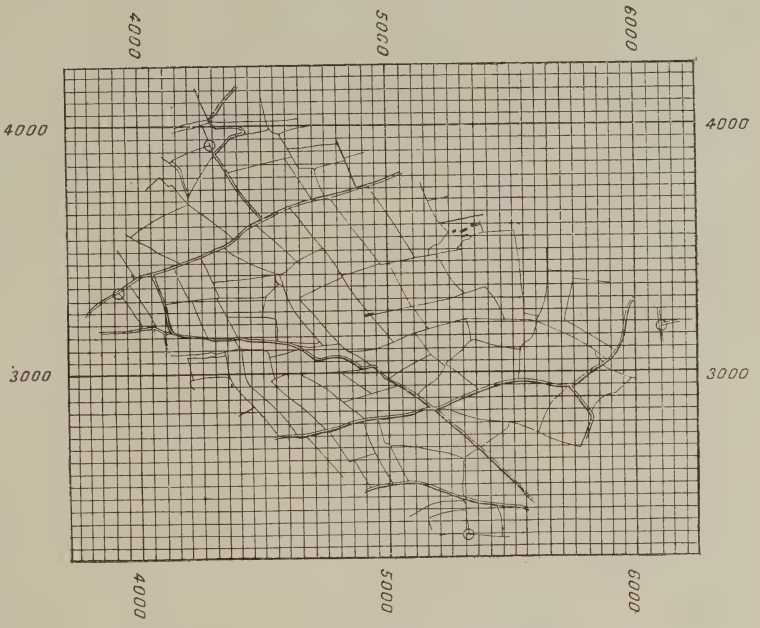

FIG. 3.—The map-grid. Reproduced, by permission of the Controller of H.M. Stationery Office, from the Report of the Air Survey Committee, No. 1, 1923.

Any one interested in the subject may be advised to purchase the Report of the Air Survey Committee, which is clearly written, well illustrated, and contains much useful information, including a short bibliography.

C. F. CLOSE.

The Reported Transmutation of Mercury into Gold.

IN NATURE of March 29 last (pp. 459-460) we printed a communication by H. Nagaoka, Y. Sugiura, and T. Mishima "on the isotopes of mercury and bismuth revealed in the satellites of their spectral lines," at the end of which the authors stated that "if the above assumption as to the mercury nucleus is valid, we can perhaps realise the dream of alchemists by striking out the hydrogen-proton from the nucleus by α-rays, or by some other powerful methods of disruption." Following this statement, on July 21 the *Morning Post* reported from Berlin that Dr. A. Miethe, professor of photochemistry and astronomy in the Technical High School at Charlottenburg, had obtained gold from mercury by the prolonged action of a high-tension electric current upon it. In the absence of details, such a report could only be received with great reserve, for in the light of existing knowledge it seemed highly improbable that the amount of energy indicated to have been used would be sufficient to disrupt the mercury atom. An account of Prof. Miethe's work containing some definite experimental details is given in the issue of *Die Naturwissenschaften* for July 18, and we reproduce these in order that the claim advanced may be justly assessed.

Some thirteen months ago, Prof. Miethe adopted an improved type of mercury-vapour lamp, made by A. Jaenicke, for his experiments on the coloration of transparent minerals and glasses induced by ultra-violet rays. Early this year, he and his assistant, Dr. H. Stammreich, observed that when the current employed was too strong, the character of the emitted rays soon changed, and that a black deposit formed inside the lamp. (It is not stated if the lamp was of quartz or of glass.) This observation was confirmed by Jaenicke, who stated that on distilling the mercury recovered from old lamps of the improved type, he had

found residues which he could not identify. He supplied Prof. Miethe with about 0·5 gram of the residues (which had been obtained from 5 kg. of mercury), and the latter after careful investigation discovered that they contained gold, in addition to other substances which were undoubtedly present as impurities in the original mercury. According to Jaenicke, all the mercury used in the lamps had been twice distilled before use. In his successful experiments, Prof. Miethe always used a potential difference of 170 volts between the electrodes, which were in direct communication with the air outside; the current was passed for 20-200 hours; and the lamp consumed 400-2000 watts. It appeared probable that a minimum P.D. is essential, for no trace of gold was found in mercury lamps of the old type that had been long in use, and negative results were also obtained with lamps of the improved type when the P.D. was below a certain figure.

Owing to the minute quantity of gold obtained, namely, 0·1–0·01 mg., special precautions had to be taken in identifying it. In every test an amount of the original mercury equal to that which was removed from the lamp was analysed and found to be free from gold both by Prof. Miethe himself and independently by K. A. Hofmann; and it was proved that no gold was present in the electrical connexions. Further, the very delicate analytical methods elaborated by Haber failed to show with certainty the pre-existence of gold. When the residue left, after distilling off *in vacuo* the mercury from the black deposit, was treated with nitric acid, there remained yellow well-formed crystals, cubical and octahedral in form, and with a highly reflecting surface; and when the mercury was removed from the deposit by volatilising it at a red heat, the resulting substance was bright gold in colour and of reniform or botryoidal shape. The substance was found to be malleable, it gave the streak of fine gold and the characteristic colour when the polished film was observed by doubly reflected light. It was easily soluble in aqua regia, and on evaporation the solution gave crystals precisely similar to those obtained when ordinary gold is so treated. Identical results were also obtained by the purple-of-Cassius test. It was not possible to make an atomic-weight determination or to attempt to prove the production of helium, hydrogen, α- or β-rays.

Obituary.

Sir James J. Dobbie, F.R.S.

JAMES JOHNSTON DOBBIE, whose death occurred at Fairlie, Ayrshire, on June 19, was born at Glasgow in 1852. He was educated at the High School of Glasgow, and entered the University of Glasgow, where he took his Arts degree with first-class honours in Natural Science. Later he worked at Leipzig in the laboratory of Wislicenus. There being no science degree at Glasgow in those days, he went to Edinburgh, and graduated as B.Sc., proceeding later to the Doctor's degree. He was elected to a Clark Fellowship at Glasgow University, and returned there and taught the class of mineralogy.

Sometime before this Dobbie had made the acquaintance of Ramsay, then a young assistant in the chemistry department of the university. Ramsay first introduced him to organic chemistry, and they read together Schorlemmer's well-known "Chemistry of the Carbon Compounds." Ramsay invited him to join in an investigation on the constitution of quinine, scarcely anything being known of the constitution of the alkaloids at that time. By oxidation with alkaline permanganate they obtained pyridine tri-carboxylic acids, which they identified, thus establishing for the first time the connexion between the alkaloids and the pyridine bases.

Soon after this Ramsay was elected to the chair of chemistry at Bristol, and Dobbie succeeded him at Glasgow. Here he continued his work on alkaloids, and also took an active share in establishing the Glasgow and West of Scotland Section of the Society of Chemical Industry, of which he was the first secretary.

In 1884 Dobbie was elected to the chair of chemistry in the newly founded University College of North Wales at Bangor. His first work was to get laboratories built and equipped, and to organise the teaching of his department. He resumed his research work on alkaloids, and made, in particular, a very complete investigation of the alkaloids of *Corydalis cava*, working out the constitution of corydaline and investigating also the structure of the associated alkaloids. This work, necessarily complicated, was rendered still more difficult by the high cost of the alkaloids, so that the investigation had to be carried out with very small quantities of material: the results were communicated in a series of papers to the Chemical Society from 1892 to 1904. A little later he took up the study of the relation between the ultra-violet absorption spectra and the constitution of organic compounds, working at first with the late Sir W. N. Hartley, and later with other workers. In particular, they showed how the method could be applied to determine the constitution of tautomeric bodies.

Dobbie's work at Bangor, however, was by no means limited to that of his own department. He felt that in an agricultural country such as North Wales, one of the proper functions of the college was to do everything possible to promote its chief local industry. He spent several vacations on the Continent studying methods of agricultural education, and started a campaign for the founding of an agricultural department at Bangor. Funds had to be collected and the interest of the land-owning classes and the farmers, as well as that of the Board of Agriculture, aroused. After several years of strenuous work the agricultural department was at length inaugurated in 1894. Courses were provided leading to a diploma and later to a degree in agriculture, while a comprehensive scheme of extension lectures and experiments was devised. This was the first agricultural department to be founded in connexion with a University College, and it is impossible to overrate the importance of Dobbie's pioneer work at Bangor in the development of agricultural education. He took a leading part in the work of the foundation of the University of Wales, and the college and the university owed much in these early days to his sane judgment and great administrative skill.

In 1903 Dobbie was offered and accepted the post of director of the Royal Scottish Museum in Edinburgh, but gave up his work at Bangor with considerable reluctance. His wide interests and scholarship combined with his administrative ability made him an excellent director. He threw himself into the work of the Museum with characteristic energy, and greatly extended the collection of Egyptian antiquities, a subject in which he was much interested. He also collected funds to acquire for the Museum the valuable Joel Paton collection of armour and antiquities, and greatly developed the technical collections. He did not, however, relinquish his connexion with chemistry, but continued his research work, a regular series of papers being contributed to the Chemical Society on absorption spectra and alkaloid work.

In 1909 Dobbie was appointed principal of the Government Laboratory in succession to Sir T. E. Thorpe, and was at once required to undertake the reorganisation of the laboratory. This was made a separate Crown Department in 1911, dealing with chemical matters arising from all Departments of State, and Dobbie was the first to hold the position of Government Chemist. Here he continued his investigations in absorption spectra and on the alkaloids. His tenure of office covered the difficult years of the War, when the strain on his department was great. He served on various commissions and committees, and in particular his services on the Royal Commission on Rewards to Inventors, the Universities Grants Committee, and the Nitrogen Products Committee may be specially mentioned. He also acted for fourteen years as adviser on the research schemes in physics and chemistry to the Carnegie Trust for the Universities of Scotland.

Dobbie was elected a fellow of the Royal Society in 1904, and in 1915 his services to science, both as an investigator and as administrator, were recognised by the King, who conferred the honour of knighthood upon him. He received the degree of LL.D. from the University of Glasgow in 1908, and that of D.Sc. from the University of Wales in 1920. He was elected president of the Institute of Chemistry in 1915, and of the Chemical Society in 1919.

The foregoing is a bare outline of a life of varied and fruitful activity. In an unusual degree Dobbie combined the patience and lucidity of the born teacher, the fertility of ideas and resourcefulness of the research worker, and the clear common sense, critical yet always constructive, of the wise administrator. In addition to all these he had much of the scholar's temperament. Reading widely, but never without fine discrimination, he was indeed the "full man" of Bacon's aphorism, and his mind was a storehouse of information over a wide range of literature and history. To the end of his days the classics were his constant solace and relaxation, and he was a living negation of the supposed antipathy between science and the humanities.

Beloved by his students and fellow-workers, in the lives of his intimate friends he leaves a blank that can never be filled. He is survived by Lady Dobbie, one son, and two daughters. ALEX. LAUDER.

WE regret to announce the following deaths:

Sir George Beilby, F.R.S., distinguished by his work in industrial chemistry, fuel technology, and many other departments of pure and applied science, on August 1, in his seventy-fourth year of age.

Dr. R. S. Woodward, president of the Carnegie Institution from 1905 to 1920, and formerly professor of physics in Columbia University, on June 29, at seventy-five years of age.

Current Topics and Events.

THE Toronto meeting of the British Association opened on Wednesday evening with the delivery by Sir David Bruce of his presidential address on the prevention of disease, which is printed in full in this week's Supplement to NATURE, together with abstracts of most of the addresses of presidents of Sections. The provisional programmes of the Sections were described in our issue of July 26, and articles upon the main subjects discussed will appear in our columns later. At the inaugural meeting, the following congratulatory message from H.R.H. the Prince of Wales was read: "Dear Mr. President, Will you be good enough to convey to the members of the British Association at their inaugural meeting in Toronto my cordial good wishes for a very successful session? My knowledge of Canada assures me that your visit will be warmly welcomed, and that nothing but good can come of such a gathering, where the representatives of the most advanced thought from the Old Country will meet in discussion the equally keen and active intellects of the Younger Land. My interest has been particularly arrested by one item that is to come up for discussion, namely, the educational training of boys and girls in this country for life overseas. The call of the Empire for a wider distribution of the home population, for men and women to open up the vast uncultivated areas in the great Overseas Dominions, is more imperative to-day than at any time in its history. I congratulate the Association on thus showing in its deliberations such a broad interest in these problems, and I trust, and indeed am confident, that the influence thus exercised may result in great and extended benefits to the Empire."

A STRIKING illustration of the attitude of Parliament and the heads of State departments towards scientific workers is afforded by an examination of the personnel of the committee appointed by the President of the Board of Trade "to inquire into and report upon the conditions and prospects of British industry and commerce, with special reference to the export trade, and to make recommendations with regard thereto." The appointment of this committee is the outcome of representations made by Sir A. Shirley Benn on May 21 in the House of Commons. On that occasion Major A. G. Church directed attention to the fact that the proposal not to include on the committee a representative scientific worker—other than economists—suggested that the House

did not realise that the greater part of the export trade of Great Britain was based upon the application of scientific discoveries. The function of the highly qualified scientific worker or technician engaged in industry is to improve industrial processes, to develop new processes, and, most important of all, to create new industries. Any national inquiry into trade must, therefore, necessarily consider the methods by which practical applications of science may be profitably encouraged. In the memorandum furnished to the Committee of Inquiry, upon which workers in science and technology are not represented, Mr. Sidney Webb states that it is their duty to make "an inquiry into British productive capacity and organisation . . . the present and future adequacy of raw materials and possible improvements in their utilisation, and the part played by the United Kingdom in new developments of industry, particularly those which are the outcome of scientific research." How such an inquiry is to be made on satisfactory lines without the assistance of those who possess a knowledge of science and its possibilities is difficult to understand. It is not enough to call scientific workers to give expert evidence; they should be given representation on the committee and share to the full responsibility for the report to be produced.

THE appointment of the Rev. Canon E. W. Barnes, F.R.S., Canon of Westminster, to the Bishopric of Birmingham, is a noteworthy sign of the times. Canon Barnes is a distinguished mathematician with wide scientific knowledge as well as a leader in theological thought, so that he represents the progressive spirit of both science and religion and combines the principles of truth and righteousness for which each should stand. In the early fifties of the last century, Robert Braithwaite Batty, second wrangler and first Smith's prizeman, gave up his promising career in England to preach the gospel, as then understood by the "evangelical" school of theology, to the natives of India. His humble missionary effort, contrary to medical advice, was closed by his death in a year's time. Canon Barnes, also second wrangler and first Smith's prizeman, is now nominate Bishop of Birmingham. The contrast is indeed strange and marks a new stage in the evolution of spiritual thought.

SIR MAX MUSPRATT, Bart., in addressing the eighth annual general meeting of the Association of British Chemical Manufacturers on July 17, said that great strides have been made recently in effecting co-operation among manufacturers and others associated with chemical industry, notably in the organisation of the chemical exhibits at the British Empire Exhibition. These exhibits have not only been instructive to students, but they have also been the means of bringing home to politicians and the public the importance of chemistry to the nation. There is considerable conflict of opinion within the Association concerning our dyestuffs policy: the council is trying to keep a balance between the opposing interests, and is advocating what it considers best for the Association as a whole. In supporting the principle of the Consolidated Factories Bill, the council approves of any measures that will make employment in factories easier and more pleasant, but it disapproves of hard and fast regulations that are unnecessary, or costly, or Utopian. Sir Max Muspratt is not hopeful that much can come out of the Rating of Machinery Bill, yet he hopes that the inquiries now being made into the general principles of rating will result ultimately in equitable treatment for chemical undertakings: the projected Census of Production will, if properly carried out, aid greatly in solving problems of unemployment, health, taxation, and rating. Sir John Brunner, Bart., referred to the Chemical Engineering Department of University College, London, and said that, although many hold that such education can produce only half-baked engineers and half-baked chemists, he thinks that there are many places in our Empire where large staffs cannot be afforded and where men trained in a chemical-engineering department could take control, if not of chemical works proper, of works in which chemistry plays a very prominent part, for example, in sugar factories.

WITH reference to our paragraph of July 19, p. 96, on the subject of trichlorophenylmethyliodosalicylic acid, it appears that this substance is to be classed among those actively germicidal owing to their inherent properties, rather than amongst those which owe their antiseptic powers to their ability to set free chlorine. The compound is very stable and its solution in water can be boiled without undergoing decomposition: it retains a great part of its germicidal action in serum. Used as an antiseptic in a 1 per cent. solution or less, it appears to owe its power to two distinct modes of action; on the one hand it stimulates the leucocytes, and thus aids the body's own defensive processes: on the other, it combines with the proteins of the bacteria by virtue of its chlorine groups; this combination is presumably with the amino-groups of the protein molecules. In this way it is attached to the micro-organisms and hinders or abolishes their activity; the phenyl and iodine radicles as well as the salicylic acid are themselves antiseptic of varying potency, and it is probable that with the attachment of the compound to the bacterial protoplasm by means of the chlorine group, the other groups are enabled to exert their action under more favourable conditions. Analgesic properties are also ascribed to it, owing to the fact that the chlorine groups are attached to the benzene nucleus. Finally, it is claimed by Dr. Callimachi that it shows little affinity for the protein molecules of human tissues, while reacting selectively with those of bacteria.

THE International Congress of Architects concluded a week's programme in London on August 2. Organised by the Royal Institute of British Architects, the meeting had for its object the discussion of architectural education, which is controlled in Britain and the Dominions by the examinations of the Royal Institute's education board. To reach the status necessary for the successful design and supervision of modern buildings requires a course of study not

ess lengthy or exacting than that required for other professions, and the requisite training is provided in architectural schools, which usually give a four years' course, during which design, construction, and the technical and legal aspects of an architect's work are the subject of study. Discussions on three successive days were centred around architectural education of the past, present, and future, under the respective chairmanships of Lord Crawford, Sir Reginald Blomfield, and Mr. Cass Gilbert (U.S.A.). In addition to a display of rare architectural books, a unique collection of students' drawings from all countries, large enough to require both Grosvenor House and Devonshire House for its accommodation, was exhibited. This is the first international meeting of architects held, and in addition to Britain and the Dominions, thirteen other countries were represented. While British schools are to be congratulated on their work, it must be confessed that the drawings of foreign countries, especially those of the United States, must be given the first place for boldness in conception and possibly also for skill in composition.

The meetings of the British Pharmaceutical Conference were held at Bath on July 22-24. At the opening session the Mayor of Bath welcomed the conference to the city, and the chairman, Mr. Edmund White, delivered an address entitled "Pharmacy: Present and Future." He first directed attention to the changes which are gradually taking place in the practice of pharmacy as the result of changes in medical practice. The *materia medica* has been enriched by the addition of a large number of synthetic substances and animal products such as gland extracts, sera, and vaccines. Pharmacists should be trained to deal with these new developments and also to undertake the newer methods of laboratory diagnosis for the assistance of the medical practitioner. Mr. White then reviewed the work of the Consultative Council on Medical and Allied Services set up by the Ministry of Health, and, from consideration of the report of that body, concluded that much of the work of the clinical laboratories, which it is proposed to set up, could be done by pharmacists. As to the Therapeutic Substances Bill, he thought that the Pharmaceutical Society should take an active part in the examination and standardisation of remedies by physiological and biological methods. The twenty-three papers read at the science meetings included: a number of communications on bismuth compounds from the Research Laboratories of the Pharmaceutical Society; a study of Benedict's method for the estimation of glucose; the preservation of anæsthetic ether; carbon tetrachloride for medicinal purposes; assay of mercurials in ointments; and papers dealing with the following drugs: tragacanth, acetannin, valerian, erythrophleum, artemisia, nux vomica, *Strychnos cinnamomifolia*, and tannin-containing drugs. The delegates from branches of the Pharmaceutical Society met under the presidency of Mr. F. Pilkington Sargeant and discussed the control of pharmaceutical specialities; also articles of pupilage, and pharmaceutical service in the Army. The programme of social events included the Civic Reception, a banquet, concerts, and motor excursions in the beautiful country surrounding the city of Bath.

The Council of the Royal Meteorological Society has awarded the Howard prize for 1924 to Cadet J. M. Goode of H.M.S. *Worcester* for the best essay on "Monsoons." The prize was competed for by cadets from the following institutions: H.M.S. *Worcester*, H.M.S. *Conway*, and the Nautical College, Pangbourne. The prize was presented to the successful cadet at the annual prize-giving on the *Worcester* on July 31.

Prof. J. C. Fields informs us that the following conferences are to be held at the International Mathematical Congress at Toronto on August 11-16: "Some of the Characteristic Features of Twentieth Century Pure Mathematical Research," Prof. W. H. Young; "Science and Engineering," Sir Charles Parsons; "Modern Norwegian Researches on the Aurora Borealis," Prof. Carl Stormer; "Solved and Unsolved Problems in Dynamical Meteorology," Prof. V. Bjerknes; "Sur l'intégration des équations aux dérivées partielles par des intégrals définis," Prof. J. Le Roux; "Sur la déformation projective des surfaces," "Sur les relations entre la théorie des groupes et la géométrie," Prof. E. Cartan; "Sur les nouveaux appareils multiplex de télégraphie," J. B. Pomey; "Principe de réciprocité dans les sciences appliquées," Prof. G. Puppini; "Géométrie algébrique," Prof. F. Severi; "Sur le calcul des variations," Prof. L. Tonelli; and "On Ballistics," General Charbonnier.

A conference, under the auspices of the British Non-Ferrous Metals Research Association, will be held at High Leigh, Hoddesdon, Herts, during the week-end September 5-8, to which are invited all who need to utilise information systematically, or are interested in the conduct or operation of information bureaux, intelligence services, and special libraries. The programme will include papers and discussions on the functions, future developments, and the methods and equipment of intelligence bureaux, and on their relations with other institutions, including national and public libraries. It is hoped to obtain representatives of such varied fields of activity as government and municipal departments, technical and research institutions, industrial concerns, financial houses, insurance offices, newspapers, and civic and social organisations, all of which have a common interest in the collection, treatment, and dissemination of facts and information relevant to their particular activities. Further information may be obtained from Mr. A. F. Ridley, Athenæum Chambers, 71 Temple Row, Birmingham.

The fifth Entomological Meeting was held at Pusa on Feb. 5-10, 1923, under the chairmanship of Mr. T. Bainbrigge Fletcher, Imperial Entomologist. The Report of its proceedings has recently come to hand, and, although it is less bulky than some of its predecessors, some sixty-one papers are included. These represent almost every branch of applied entomology and afford ample testimony of the importance the subject has attained in India. The institution of meetings of this description brings together workers

who are often isolated at great distances apart with little or no opportunities of direct intercourse. The means thus afforded for the ready interchange of information and ideas also attains a more lasting value by the publication of these very fully illustrated Reports. Among the various papers included in the present volume, one of the most important is that by Mr. T. Bainbrigge Fletcher on the possible introduction of the American cotton boll-weevil into India. It appears that the risk of this pest securing a footing in that country is very real, and, after considerable discussion, the Conference passed a resolution that the Indian Central Cotton Committee should consider the advisability of recommending the total prohibition of cotton from America. As an alternative, it is suggested that all bales containing such cotton should be confined to Bombay. The subject of the teaching of entomology in the Indian universities also came up for discussion. The meeting recommended and passed a resolution to the effect that entomology be taught as of equal rank with other branches of biological science in the courses of study for the examinations for degrees in science, including agriculture.

A FISHERY expert is required by the New Zealand Government for co-operation with the chief inspector of fisheries. Particulars of the appointment and form of application may be had from the High Commissioner for New Zealand, 415 Strand, W.C.2. The completed form must be returned by, at latest, August 23.

SOME appointments are about to be made in connexion with the Fuel Research Station, East Greenwich. Candidates must be honours graduates in chemistry (or have equivalent qualifications) with experience in the technology of fuels; or be honours graduates in engineering (or have equivalent qualifications) with similar experience. Research experience is essential for a higher post in chemistry, and industrial experience for a higher post in engineering. Applications must be made on a form obtainable from the Department of Scientific and Industrial Research, 16 Old Queen Street, S.W.1, returnable not later than August 20.

THE American Oil Chemists' Society has established a new quarterly journal which will be the official journal of the oil and fat industry in the United States. The new publication will deal with the chemical considerations of oils, fats, and related materials such as oil meal feeds and fertilisers, paints, soaps, foods, and packing-house products. H. S. Bailey, chief chemist of the Southern Cotton Oil Company, heads the board of editors, composed of the leading American chemists in this field. The first number is to appear this month from the press of the publishers of the American Chemical Society publications. Correspondence regarding subscriptions should be sent to Fred H. Smith, Managing Editor, Experiment, Georgia, U.S.A.

THE Wisconsin Survey Bulletins Nos. LII. and LIV. include a general soil survey of the south part of North Central Wisconsin, and a detailed survey by counties of the southern and older portions. Each section is preceded by a general description of the area concerned, with a summary of the various series of soils found in the district. These groups are then treated in detail, special attention being directed to the economic aspects, such as topography and drainage, native vegetation, and the present state of agricultural development. Each survey is illustrated by an excellent soil map to which a legend is appended in which the soils are grouped according to their surface features and drainage, and are further classified in accordance with their uses and adaptation, fertility, and methods of improvement.

A NEW and much more convenient *format* has been adopted by the Ministry of Agriculture and Fisheries for its fishery publications: it is understood that this is a very great reform, accomplished with difficulty. Three papers are noticed here: Vol. 6, No. 1, a study by Dr. E. S. Russell of the seasonal variations in the chemical composition of the oyster. The paper is based on a large series of analyses made by the staff of the Government Chemist. Vol. 6, No. 5, by J. N. Carruthers, deals with the "intensive" plaice investigations of 1921, particularly the marking and transplantation experiments. Vol. 7, No. 1, is an account of the development of the cod by Prof. A. Meek. The author has been able successfully to make sections of developing cod eggs—a result of considerable value—and has evidently made a contribution of importance to the study of teleostean embryology. This embryological detail has, however, been omitted from the paper "as unsuitable in a fisheries publication," and the figures and results actually included are mainly such as have long been familiar in fisheries reports—pictures of fish embryos as seen through the outer membranes and useful only for the purpose of identification of the eggs.

THE Leicester Museum, Art Gallery, and Library Bulletin, of which the first number was issued in June, is in itself a token of progress. It announces another advance in the experimental appointment of Miss F. A. Rogers as guide demonstrator to all three institutions; the extension of this service to the libraries of the town is, we believe, a novelty. The main object of the Bulletin is to direct attention to recent accessions. Those mentioned in the present number comprise an ancient Egyptian funeral boat of the XII. Dynasty, a single-handed turret clock of about A.D. 1700 from Aylestone Church, a bronze, "The Mourning Woman," by Epstein, and a number of books on hosiery manufacture and the related textile industries. The Bulletin is intended, for the present, to be distributed gratis at quarterly intervals.

A BEAUTIFUL album of views in the Canton of Graubünden or Grisons has reached us from the Grisons Tourist Information Office, Coire (Chur), Switzerland. The album includes striking illustrations of Klosters and the Canardhorn, Arosa, Flims-Waldhaus with its lakes and pine-woods, St. Moritz, Silvaplana, Maloja, the Morteratsch glacier, the fine Bernina Pass to Alp Grun with the valley and the lake of Poschiava below, the National Park, Pontresina, and many other places in the Upper and

Lower Engadine. Few areas in Switzerland can offer such a variety of interest and charm as the Engadine. There are mountain peaks, glaciers, well-shaded walks, and lakes, while the remarkable railway, going to a height of 7400 feet, from St. Moritz to Tirano, with conveniently placed stations, make most of the beauty spots in the district easily accessible to visitors who are not mountaineers or cannot undertake long excursions in the high Alps. In the Engadine the mountains are wooded to a greater height than anywhere else in the Alps, and as the general level is about six thousand feet, the district has advantages over most of the places visited by tourists. Pontresina is one of the best centres, and a holiday spent there cannot fail to be of benefit to both body and mind.

MESSRS. DULAU AND CO., LTD., have just circulated a catalogue (No. 114) of books and papers on conchology, mollusca, and minor classes—recent and fossil. Upwards of 1300 titles are given in the list, which will doubtless interest many readers.

READERS of NATURE on the look-out for bargains in books should obtain Catalogue No. 237 from Messrs. W. Heffer and Sons, Ltd., Cambridge, in which are given the titles of many books of science now offered for sale in new condition at greatly reduced prices—the books being "remainders."

WE have received from the British Dyestuffs Corporation, Ltd., a price list of fine organic chemicals for research work, indicators, microscopic stains, and medicinal and photographic chemicals. A very extensive range of products at reasonable prices is available, and it is evident that great progress has been made in the fine chemical industry.

MESSRS. H. K. LEWIS AND CO., LTD., 136 Gower Street, W.C.1, have just issued, at 1s. net, a supplement (1921–1923) to the catalogue of their Medical and Scientific Circulating Library. It should be very useful, not only to users of the library, but also to students in general of scientific literature, being practically a list of the science books published during the period named, consisting of a classified index to subjects in addition to the catalogue itself, which is arranged alphabetically under the names of the authors. It gives the date of publication of the volumes included.

MESSRS. W. H. HARLING, of 117 Moorgate, London, have just issued a new illustrated catalogue of drawing instruments, mostly of their own design and manufacture. These include, besides the usual group of engineers' drawing materials such as scales, parallel rules, T-squares, set squares, drawing boards, etc., a few more elaborate instruments, such as pantographs and eidographs, which should appeal to the increasing number of people who frequently resort to graphical methods. There is a cheap new pantograph which enables drawings and plans to be reduced by sixteen different ratios and enlarged to four times. A more expensive but much more accurate instrument is the eidograph, designed to provide the accuracy required for fine details of map construction. The instrument will enlarge with this accuracy up to a ratio of 1 in 4.

ERRATUM.—Dr. H. O. Forbes writes: "By a very regrettable oversight in correcting the proofs of my communication in NATURE for August 2, 'Pre-Columbian Representations of the Elephant in America,' Dr. Maudslay's name was misspelt Maudsley."

Our Astronomical Column.

ENCKE'S COMET.—This comet was detected on its return by Prof. G. van Biesbroeck at the Yerkes Observatory on July 31. Its position at $20^h\ 45{\cdot}6^m$ G.M.T. on July 31 was R.A. $3^h\ 24^m\ 53{\cdot}4^s$, N. Decl. 28° 6′ 27″, Magnitude 16·0. The position is within 1′ of Matkiewicz's prediction, according to which perihelion will be reached on Oct. 31·42 G.M.T. The comet should become visible to ordinary telescopes in the last week of August.

THE TOTAL LUNAR ECLIPSE OF AUGUST 14.—We are passing through a period of eighteen years (1920–1938), during which no total lunar eclipses are visible in England under really good conditions. That on August 14 will, however, give some opportunities for observation, especially towards the close of totality. Sunset is at 8.25 P.M. (summer time), the middle of eclipse at 9·20, the end of totality 10.9, last contact with umbra 11.9. The eclipse is nearly central, its magnitude being 1.66 in terms of the moon's diameter. The degree of illumination, and colour, of different portions of the eclipsed moon should be studied, since they give interesting information as to the transparency of the terrestrial atmosphere. Total eclipses can also be used for obtaining improved values of the moon's diameter, by observing the occultations (both disappearance and reappearance) of faint stars. This requires co-operation between a large number of observers; the moon will be too low for observations of this kind in Europe, but some lists have been prepared for southern observers.

A NEW FORM OF ORRERY.—The *Times* of July 31 describes a very interesting method of demonstrating celestial phenomena which is being installed in the Deutsches Museum at Munich. It was constructed by the well-known optical firm, Messrs. Zeiss, of Jena, and consists of about forty optical projectors which throw images of the various heavenly bodies on the white inner surface of a spacious dome. Their relative movements and changes of aspect can be exhibited in an instructive manner.

The ordinary cinematograph can be usefully employed as an aid to astronomical education. It will be remembered that Mr. Maskelyne took a successful film of the total solar eclipse of May 1900 (exhibited at a meeting of the Royal Astronomical Society), and the attempt was repeated in Australia in 1922; but no one seems yet to have realised the possibilities of the method in explaining elliptical or parabolic motion, or various other points in which a moving picture would give far more convincing demonstration than the ordinary diagrams of the text-books.

THE PREPARATION OF THE "GESCHICHTE DES FIXSTERNHIMMELS."—Prof. R. Schorr writes to say that the preparation of this work is being continued at Berlin, Prof. Paetsch having been appointed by the Prussian Academy of Sciences to superintend it. Prof. Schorr is making an independent study of the proper motions of the stars contained in the published volumes (R.A. 0^h to 2^h). The note in this column on July 12 gave the erroneous impression that he was taking a part in the Geschichte itself.

Research Items.

THE ANTIQUITY OF MAN IN CALIFORNIA.—In *Science* for July 4, Dr. John C. Merriam, in surveying the results of the investigations into the question of the antiquity of man in California carried out by the University of California during the last twenty-five years, points out that the Californian coast region has been in almost constant movement throughout the later geological periods and thus affords a continuous record of the processes of erosion and deposition and of the life of the region during these times. Four lines of investigation have been followed :—(1) the shell-mounds have been examined from the deposits of known culture to those of the earliest times ; (2) cave deposits have been explored ; (3) pleistocene and recent land, stream, lake and marine deposits in which human remains are likely to be found have been studied ; and (4) the evidence relating to the occurrence of human remains or implements in gold-bearing gravels or other ancient deposits has been reviewed. Up to the present, all human remains discovered belong to the type which has been recognised as "modern" and none belong to a geological formation older than the recent period. In the same issue of *Science*, Dr. Chester Stock follows with an account of the geological conditions in which the skeletal remains of six individuals were found in the course of the construction of a sewer at Los Angeles in March last at depths of 18 ft. and 23 ft. The skulls, so far as they have been compared, are of modern type. Some of the remains are considerably mineralised. They present the appearance of having been mired in under bog or marsh conditions rather than washed in. No pleistocene or recent mammals were associated with the human remains, but a comparison with similar deposits in the immediate vicinity suggests the probability of a date later than pleistocene, though of considerable antiquity.

NEW SPECIES OF SHIPWORMS IN BERMUDA.—As part of the inquiry taking place in the United States on the activities of shipworms, Dr. E. L. Mark, Director of the Bermuda Biological Station, installed test-boards at four stations in Bermudan waters. The specimens of shipworms which attacked these blocks have been examined by W. F. Clapp (Proc. Amer. Acad., Arts and Sci., vol. 59, 1924). He reports that the attacks were not so severe as those caused by shipworms at Key West, Florida, and in the West Indies, but the ravages by Limnoria were so extensive that the posterior ends of many of the shipworm tubes were soon exposed to the action of the water, resulting in the premature death of many of the shipworms, so that specimens of large size were rare. The destruction caused by Limnoria was found to be about an inch in twelve months. Of the six species of shipworms received in the test blocks three are new ; descriptions of two of these are given, but the author desires further material for the study of the third species before giving an account of it. The genus Bankia (Xylotria) is not represented either in the present collections or in any previous records from Bermuda.

ADDITIONS TO THE BRACKISH WATER FAUNA OF SPAIN.—There is still much to be done in the investigation of brackish water faunas throughout the world, and if the curious discoveries of Enrique Rioja, in the Rio de San Nicolás at Gandía on the west of Spain, are to be taken as typical the investigations will yield some startling results in geographical distribution. He found, in the first place, in the streams debouching in the harbour of Gandía, colonies of a small serpulid worm which spread over stones, gre on the submerged keels of old boats and such lik The serpulid he identifies as *Mercierella enigmatic* a species described by Fauvel, in December 1922, ; occurring in the brackish water of the canal at Cae the only place where it has been found until no Rioja gives a good description and some excelle figures of the species. (Bol. Real Soc. Espag. His Nat., tome xxiv., 1924, p. 160-169.) But growi amongst the tubes of Mercierella was a more remarl able form, a minute hydroid which the auth identifies with *Annulella gemmata*, a new genus an species minutely described by Ritchie from colle tions made at Port Canning, Bengal. The characte of the two forms agree ; in Bengal, as in Spain, t species frequented brackish water ; and in Spa Rioja has been able, as Annandale was in India, keep examples alive in the laboratory in a mixtu of sea and fresh water. This occurrence of Annulell so far distant from its original place of discover indicates either a very widespread distribution brackish water species, or possibly an environment effect of this particular medium, inducing clos convergence of structure, in forms not necessaril directly related.

THE SYMBIOTIC ORGAN IN APHIDS.—In his studi on the development of Aphids, L. B. Uichanc (*Philippine Journ. Sci.* vol. 24, No. 2, 1924) dea especially with the history of the symbiotic organ mycetom. The follicular epithelium of the ovar apparently becomes infected with the symbiont which remain in a dormant condition until stimulate to multiplication by the development of the egg. Th symbionts break through the follicular epithelium an invade the embryo and especially the vitellophags— which the author calls mycetoblasts. The relation these to the inflowing granular mass—suggestive phagocytosis—lends support to the view that th symbionts are extraneous organisms and not by products of the insect's own metabolism. Th mycetoblasts form a globular mass in which definit cellular differentiation takes place shortly befor segmentation of the germ-band, some thirty t seventy mycetocytes being produced. After birth the aphid, the mycetocytes, which lie in the abdomina cavity, do not further divide, but they increase in siz and the symbionts multiply. In the adult aphid, th mycetocytes begin to degenerate one by one until a the end of life very few remain. The mycetom i present in every aphid whether male, female, o parthenogenetic. In its development, the aphid eg differs from that of related groups in that the peri plasm and afterwards the blastoderm leave an openin at the posterior pole so that there is direct communica tion between the follicular epithelium and the eg cavity. The author regards this as a special adapta tion by which the symbionts are enabled readily t enter the egg cavity.

ESTIMATION OF WIND ABOVE FOG.—Mr. L. F Richardson has devised a method for use in estimatin the wind above fog or low cloud which he describes i Meteorological Office Professional Notes, Vol. 3, No 34. The procedure is relatively simple. In th middle of a large uninhabited field a steel roof i supported on posts. The observer shelters under thi roof, through a hole in which is projected a smooth bore gun. The gun is mounted on a special mountin which enables the observer to vary its tilt. The aim of the observer is to vary the tilt in such a way tha the ball which is fired from the gun falls on the roof

The tilt which attains this object is called the balancing tilt, β, and it is read in two components, the components which Mr. Richardson designates by β being the cosines of the angles between the axis of the gun and the east-west line and the north-south line respectively. The gun is first loaded with a steel ball and sufficient powder to carry the ball up to a moderate height, say 100 m. By trial and error, and the use of a table giving corrections to β necessary to correct certain errors in point of fall of the ball, the tilt necessary to bring the ball back down on the roof of the shelter is evaluated. The charge of powder is then increased so that a greater height is attained, and so on by successive stages. The limit of height attained by Mr. Richardson appears to have been about 750 m. The height attained by the ball is evaluated by noting the time of absence of the ball, *i.e.* the time from firing until the return impact on the roof. The raw material of observation thus consists of certain times of absence with the corresponding values of β in two directions. The computation of winds at different levels is carried out by the use of certain formulæ given by Mr. Richardson in a paper in Phil. Trans. R. Soc. A. Vol. 223, "Theory of the Measurement of Wind by shooting Spheres Upward." The process is quite straightforward and simple. The paper before us does not indicate the degree of accuracy which may be expected from such observations.

THE RADIOACTIVE CONSTANT OF RADON.—In the *Comptes rendus* of the Paris Academy of Sciences, May 26, Mlle. I. Curie and Mlle. C. Chamié describe a new method of determining the above constant. Suppose two bulbs could be obtained, containing exactly equal quantities of the gas, in equilibrium with the rapidly evolved active deposit; one of them is placed in an ionisation chamber and produces a current i, which decreases with the time. The instant t when i passes through a certain value a is observed, and then the two bulbs are placed together in the chamber, and the instant t' observed when the ionisation current again passes through the value a; then $T = t' - t$ is the half life period of radon. In practice, it is not possible to obtain two bulbs with exactly equal quantities of the gas; but it is shown that if the quantities q_1 and q_2 at time o are nearly equal ($q_1 < q_2$), and the times t_1 when one bulb produces the ionisation current a, t_2 when the other bulb produces the same current, and t', when the two bulbs together give a, are determined; then $T = t' - \frac{1}{2}(t_1 + t_2)$. Details of the experimental method employed are given, and the results of four determinations agree to 0·1 per cent., giving $T = 3{\cdot}823$ days with an accuracy equal at least to 1 in 2000, and probably higher than this. Mme. Curie found $T = 3{\cdot}85$ in 1910, Sir E. Rutherford confirmed her value in 1913, and Bothe and Lechner determined $T = 3{\cdot}810$ in 1921.

DISTRIBUTION OF ENERGY IN THE SPECTRUM OF A MERCURY ARC.—M. G. Athanasiu describes in the *Comptes rendus*, Paris Acad. Sci., June 16, measurements of the energy of a number of lines in the spectrum of the mercury arc, with different electrical inputs. The observations were made by means of a thermopile and galvanometer. The lines of the first triplet of the sharp series, the three groups of lines forming the first triplet of the diffuse series, and the three groups forming the second triplet of that series were investigated. The group of yellow lines 5769-90 was also measured. Inputs from 100 up to 300 watts were employed. The energy curves of lines belonging to the same series have the same general appearance, and the ratio between the intensities of two lines of the same series remains nearly constant when the watts are varied. The deviations in the case of the first triplet of the sharp series are not larger than the experimental error (3 per cent.). In the case of the diffuse series the deviations are somewhat larger; this might be expected, since each of these groups contains a line belonging to a different series, the combination series $1p - Dm$ (Fowler). For two lines belonging to different series the ratio of the intensities varies with the watts between large limits, and may be inverted, the energy curves cutting one another. The ratio of the intensity of the yellow group to that of the green line, $\lambda 5460$ (the first line of the first triplet of the sharp series), changes in the lamp studied from 0·5 for 100 watts to 1·25 for 300 watts.

THE NUMBER OF α-PARTICLES EMITTED BY RADIUM.—In the *Zeitschrift für Physik*, June 12, V. F. Hess and R. W. Lawson criticise a recent paper by Geiger and Werner, who have obtained for the above number $3{\cdot}4 \times 10^{10}$, agreeing with the value originally found by Rutherford and Geiger, but differing from Rutherford's later value, $3{\cdot}57 \times 10^{10}$, and from that found by the authors in 1918, $3{\cdot}72 \times 10^{10}$. It is suggested that the platinum used in the construction of the container employed for the emanation, which had to be heated in the course of filling, occluded emanation when cooled; this might easily produce an error of 10 per cent. It is doubtful whether Geiger and Werner are correct in thinking that their scintillation screen, in which powdered zinc sulphide was mixed with castor oil or turpentine oil, gave scintillations corresponding to almost 100 per cent. of the total α-particles, as was the case with the zinc sulphide alone (99·6 per cent.). The method adopted for obtaining the true number of scintillations from the counts is criticised, and the authors conclude that their own previous result is more trustworthy. It agrees much better with estimates derived from the amount of heat produced by the disintegration of radium, the difference being perhaps due, as suggested by Geiger and Werner, to energy liberated in consequence of structural alterations in the nucleus. This energy is not likely to be so large as would be indicated by Geiger and Werner's number.

THE PRODUCTION OF SULPHURETTED HYDROGEN BY FERMENTATION IN THE BLACK SEA.—Six cubic centimetres of hydrogen sulphide per litre has been found at a depth of 2970 metres in the Black Sea, and it has been suggested that this is due to the decomposition of organisms which are brought in by currents from the Mediterranean and killed by the alteration in the salinity. Sulphates in the water would also be reduced, with the formation of hydrogen sulphide. Zelinsky and Brousselovsky ascribed the phenomenon to the action of a definite organism, *Bacterium hydrosulphureum ponticum*, on the sulphate; but Nadson considers this bacterium to be an ordinary putrefactive ferment, *Proteus vulgaris*. Mr. B. Issatchenko, who gives the above particulars in an article in the *Comptes rendus* of the Paris Acad. Sci., June 23, has recently taken part in a voyage of exploration in the Black Sea, and has found a small characteristic vibrion, with all the characteristics of *Microspira aestuarii*, and probably identical with this organism. It grows abundantly under anaerobic conditions, without the presence of any albuminoid substance, in a solution containing salts of organic acids and sulphates, producing 0·3 to 0·5 of hydrogen sulphide per litre. Issatchenko considers it probable that the hydrogen sulphide in the lower layers of the Black Sea is largely due to this organism.

The Scottish Cattle Breeding Conference.

THE student of agriculture now passing through the schools is receiving an introduction to the newer sciences that have their applications in agricultural practice, but from the older generation of stock-breeders the recent advances in these fields of inquiry are completely hidden and, before their conservative indifference towards science can be overcome, much work of an educational nature must be undertaken. It was for the purpose of displaying recent achievements in the field of agricultural physiology that the Scottish Cattle Breeding Conference, held at Edinburgh on July 7-12, was convened. It was intended also to show to the breeder part of the State schemes of research in relation to agriculture in operation.

The Conference was undoubtedly an event of outstanding interest in the history of livestock breeding in Great Britain and can be accounted a success, although, as was anticipated, British breeders did not attend in large numbers. It was not to be expected that the man who regards himself as a successful breeder could easily be attracted by a scheme that had for its object the systematic collection of information that would help to make breeding successful. As the days of the Conference passed it became increasingly clear that there exists a great gulf between the scientific worker and the breeder that cannot easily be bridged. Each speaks a tongue that is foreign to the other, and the outstanding need in British agriculture to-day is the scientifically trained agricultural journalist who shall interpret the work of the man of science to the breeder. The programme was so arranged that full opportunity was given to both to learn each other's language and to see each other's point of view and methods. A great deal of time had to be spent in discussing the very A B C of genetical science, and there can be no doubt that had these hours been available for more advanced matters the Conference would have been more profitable.

The speeches of the chairman of the Board of Agriculture for Scotland, the Lord Provost of Edinburgh, the Secretary of State for Scotland, the president of the Shorthorn Society and of Dr. Robert Wallace, emeritus professor of agriculture in the University of Edinburgh, at the opening session, created just the atmosphere in which the free interchange of experience flourishes, and the stage was set for the business of the five following days.

Early in the proceedings Major E. N. Wentworth, a geneticist of repute and the present head of Armour's (Chicago) Livestock Bureau, outlined the relations between the science of genetics and practical breeding. He explained the reasons why the spectacular advances in the pure science have not been quickly followed by parallel advances in the craft, and why genetical knowledge is not likely to affect, at all profoundly, breeding procedure. The reasons are financial in nature. Genetical knowledge can best be employed in the creation and development of new breeds, but this work is made quite prohibitive because of the expense and the length of time required. It is a matter of the greatest difficulty to displace the already established even with a more satisfactory breed, and almost impossible to overcome tradition.

Major Wentworth mentioned one matter of considerable interest. The American consumer is exhibiting an ever-increasing demand for baby-beef (yearling cattle), whilst the producer, disregarding this demand and certainly fighting a losing battle, is still intent on breeding for increased size. The problem of meeting the demands of the consumer is to be tackled by the geneticist and breeder working in collaboration.

Dr. Chr. Wriedt, of Kristiania, in a paper on the inheritance of abnormal conditions, opened up a subject of profound importance to the livestock industry. During the discussion that followed it was pointed out that any characterisation, detrimental to the individual, which behaves in a mendelian fashion in inheritance is a character in the mendelian sense, and can be eradicated from a stock only by the adoption of mendelian methods of breeding. Already a considerable number of such characters that render the possessor non-viable or more or less imperfect have been recognised. Monstrous calves, deformed lambs, still-births, certain forms of sterility, of blindness, and of deafness, white heifer disease, hermaphroditism, undescended testis, skin defects, and many other conditions, have been shown to be mendelian characterisations, and it can be expected that the list will be considerably augmented when the veterinarian and the breeder recognise that the present-day knowledge of the hereditary mechanism has been gained through the study of the inheritance of similar conditions in the usual laboratory animals. It is probable that a great proportion of the anatomical defects and physiological derangements that are found in cattle will be shown to be mendelian characters.

Prof. L. J. Cole, chief of the Animal Husbandry Division of the U.S. Bureau of Animal Industry, in one of his many papers dealt exhaustively with the vexed question of the effects of inbreeding, maintaining that the harmful effects depend entirely upon the hereditary constitution of the individuals concerned and not upon any pernicious attribute of inbreeding in itself. There is a great deal of evidence which supports this contention, but the unfortunate fact remains that it is not possible for the geneticist to be really helpful in this matter. It is unwise to advise the breeder to undertake inbreeding in order to achieve rapid improvement in his stock, when the records of so many domestic breeds show that the individuals are carrying factors for harmful recessive characters which would quickly be disclosed were in breeding practised. It is true that by this method of breeding a stock could be purged of its undesirable characters, but it is equally true that during the process the stock might become extinct. In certain cases stockbreeding has become one sustained effort to retain heterozygosity in order that undesirable characters may not be expressed, and the homozygosis that follows inbreeding is the last thing that the breeder desires.

Two papers of great interest which roused great enthusiasm among the breeders were those on the reproductive functions and on the development of the udder in the cow, given by Mr. J. Hammond, of the Cambridge Institute of Research in Animal Nutrition, and these led the way to a discussion on milk-recording which was opened by a paper by Mr. B. A. Sanders, of Cambridge. The breeder was shown clearly how difficult the genetical interpretation of milk records is made by the efforts of the husbandman. Until all variations of extraneous origin are accounted for the genetical basis of milk yield cannot be begun, and even then it is to be expected that this will prove to be a very complicated multi-factor affair.

There is no doubt that shortly some modified system of advanced registry will be adopted in Great Britain in the recording of milk cattle. Mr. Mackintosh, of the National Institute for Dairying, Reading, helped

on this movement considerably by his plea for a uniform system of stating milk and butter-fat records. He pointed out that the present lack of uniformity renders comparative studies impossible, seriously embarrasses the breeding of dairy stock, and denies the overseas buyer those data to which he is entitled. He urged that the lactation period of a cow should be recorded in days; that the date of the next calving and details as to whether a full-time calf had been born should be stated; that the records of the milk-yield should be based on weighings at not more than weekly intervals and should be stated only in pounds; that the records of butter-fat should be based on a sufficient number of samples taken at fairly spaced intervals during the lactation period, and that the total weight of the butter-fat produced should be stated in pounds. The conference unanimously supported Mr. Mackintosh.

The fifth day of the meeting was given over to papers by the breeders, who were asked to define their problems. Most of the difficulties presented were such as are at the present time quite beyond genetical analysis, for they concerned highly improved expensive stock, and in many instances passed far into the realms of veterinary medicine. Nevertheless certain of the breeders' problems are problems no longer, and it was very satisfying to the geneticist to be able to explain away the lesser difficulties which still harass the breeder.

During the whole of the week the discussions were eager and the audience insatiable for information. It was shown quite conclusively that this was to be but the first of many such meetings. Before the next, however, it is to be hoped that the Journal of the Ministry and of the Board of Agriculture for Scotland, and also the series of monographs now being issued by the Ministry, will find their way into the hands of many more of the breeders of Great Britain, and that the geneticist will be co-opted on the councils of the various breed societies. F. A. E. CREW.

The Imperial Mycological Conference.

ON July 2, mycologists from all parts of the British Empire met in conference at the Imperial College of Science, South Kensington. It was the first gathering of its kind, and marks a distinct advance in organising the campaign against fungous diseases of agricultural and plantation crops. The conference was called by the Colonial Office to discuss the future arrangements for the Imperial Bureau of Mycology, but a large part of its time was taken up with interesting and useful discussions on various aspects of plant disease work throughout the Empire. Official delegates represented most of the Dominions, Colonies, and Protectorates, while the members of the Committee of the Bureau attended the meetings, as well as a number of mycologists from the British Isles who were invited to be present. On the afternoon of July 2 the delegates were entertained to tea at the Bureau, and on the evening of July 4 the British Mycological Society acted as hosts at a dinner given to the overseas mycologists in the Criterion Restaurant. The conference had been arranged to precede the Imperial Botanical Conference, which was held the following week, and the delegates had the opportunity of taking part in the meetings and excursions arranged by the latter conference.

Earl Buxton, chairman of the Committee of Management of the Bureau, received the delegates, and in his opening address spoke at length of the founding of the Bureau, the scope of its work, and the economic importance of plant diseases. The rest of this day, as well as the last part of the closing meeting, was spent on business matters.

On Thursday, July 3, under the presidency of Mr. W. Nowell, Assistant Director of Agriculture, Trinidad, Mr. Tattersfield (Rothamsted) opened a discussion on "The Co-ordination of Investigations of Fungicides," expressing the view that the explanations of fungicidal action are, in general, inadequate, and that research should attempt to correlate chemical constitution with toxic action. The subject gave rise to an animated discussion in which Dr. Brierley (Rothamsted), Mr. Dowson (Wisley), Dr. Wormald (East Malling), Mr. Briton-Jones (Long Ashton), Mr. Massey (Sudan), Mr. Nowell, Mr. Summers (Shirley Institute), and Dr. Butler (Bureau) took part, and finally the suggestion, made by Dr. Brierley, that a committee be appointed for the co-ordination of work on fungicides was referred to the Managing Committee of the Bureau for consideration. The second half of this session was occupied with the consideration of "Plant Disease Surveys in the British Empire." Dr. Butler, who introduced the subject, spoke of the many ways in which plant disease surveys are invaluable aids to the phytopathologist. Mr. A. D. Cotton (Kew) described the origin and development of the survey of England and Wales and emphasised the importance of a survey for the agricultural progress of any country. Dr. Shaw (India), Mr. Gadd (Ceylon), and Dr. Doidge (South Africa) reviewed the survey work being done in their respective countries.

In the afternoon, Dr. Pethybridge (Ministry of Agriculture) in the chair, Mr. Cunningham (New Zealand) spoke on "The Standardisation of Popular and Scientific Nomenclature in Plant Pathology." He illustrated the necessity of standardisation by a few well-chosen examples, and showed how the multiplication of common names, especially for those diseases of which the causal organisms are not known, must lead to confusion. The considerable divergence of the scientific names adopted by different workers, as well as their frequent change, is also liable to cause trouble. Mr. Cotton stated that the Phytopathological Committee of the British Mycological Society had undertaken the work of the standardisation of common names in England and enunciated the principles the committee had decided to adopt. Dr. Murphy (Irish Free State) suggested that some understanding with the United States should be reached on the subject. Various speakers mentioned the importance of the popular name in dealing with the farmer.

The next paper was one by Mr. Tunstall, of the Indian Tea Association, on "The Encouragement of Private Enterprise in the Investigation of Plant Diseases." After describing the development of the scientific department of the Association, which had more than satisfied the tea planters with the results obtained, the speaker expressed the view that continuity of the work was essential and the use of highly paid specialists for short periods unsatisfactory. The Government could encourage non-official enterprise by means of grants, and in return should have a call on the services of the enterprise. Dr. Butler spoke of the excellent work being done by private enterprise in various parts of the world, and considered that such enterprise need not clash with Government institutions. Mr. Gadd outlined the rubber research scheme established in Ceylon in conjunction with the Rubber Growers' Association. Col. French (Empire Cotton Growing Corporation) gave an account of the work of the Corporation, and Dr. Pethybridge mentioned the enterprise of the glass house industry near London in this respect.

The morning session on Friday, July 4, when Prof. J. B. Farmer (Imperial College) and later Mr. Stockdale (Ceylon) presided, was occupied wholly with diseases of tropical plantation crops. Dr. Doidge gave an account of the campaign to eradicate from South Africa the canker of citrus trees (*Pseudomonas citri*), which was probably introduced on some Japanese stocks. The cost of the campaign to date was 117,000*l.*, and though it was too early to be sure that the disease was completely stamped out, the results were promising. Various other citrus diseases were briefly reviewed. In the discussion which followed, Mr. Nowell expressed the opinion that the present campaign in South Africa, if successful, would no doubt have a considerable reaction throughout the world. Mr. Massey followed with a paper on "The Cotton Diseases occurring in the Sudan," dealing particularly with the outbreak of *Bacterium malvacearum* in that area. The disease is seed-borne, and the problem of control essentially one of seed disinfection, which is being carried out on a large scale with this year's seed. The discussion was largely concerned with this disease, but Mr. Briton-Jones (formerly mycologist in Egypt) spoke of the diseases occurring in Egypt, and Mr. Summers of the mildewing of cotton fabrics. Prof. S. F. Ashby (Trinidad) was responsible for leading the discussion on "The Panama Disease of Bananas." After an account of the disease and of the very heavy losses caused by it, especially in Central America, the speaker showed that the real solution of the problem of fighting it was the discovery of an immune variety; the work with this end in view, now in progress at the Imperial College of Tropical Agriculture, was described. Mr. Hansford described the position of affairs in Jamaica with regard to this disease. In the afternoon Mr. Bunting spoke on "The Diseases of Cacao in the Gold Coast," mentioning particularly the newly discovered cocoa parasites of that Colony.

A subject of fundamental importance was raised by Mr. Nowell, on Friday afternoon, in his paper on "The Influence of Soil Conditions on Plant Diseases." The speaker put forward the view that many diseases of plants are primarily due to soil conditions and that the fungi are only parasitic when these conditions render the hosts susceptible. Diseases of this nature could be classified as root diseases and debility diseases. Numerous examples were given, particularly root rot of sugar-cane, which has been ascribed to various fungi and which can be completely overcome by good manuring. In the vigorous discussion which followed, Mr. Tunstall strengthened the views advanced by citing additional examples from his experience of tea diseases, and Dr. Shaw spoke of the differences in the incidence of the wilt of pigeon pea on the permanent manurial plots at Pusa in India.

At the closing session of the conference on Saturday, July 5, Mr. Nowell presided, whilst Dr. Shaw and Dr. Murphy addressed the meeting on "The Application of the Results of Mycological Investigations," the former from the point of view of the tropical countries with a native population, and the latter from that of temperate countries with white farmers. Dr. Shaw described the organisation of the agricultural service in India to deal with plant diseases and the methods adopted for conveying information to the cultivator. A full discussion followed, in which Mr. Bunting, Miss Welsford (Zanzibar), Dr. Butler, Dr. Doidge, and Mr. Stockdale took part. The last part of the closing session was occupied with business matters, Sir David Prain being in the chair, and a number of resolutions were passed dealing chiefly with the establishment and finances of the Bureau, and recommending that similar conferences should be held every five years.

University and Educational Intelligence.

CAMBRIDGE.—The Research Studentship offered annually by Trinity College to a graduate of another university who intends to come to Cambridge with a view to the degree of Ph.D. has been awarded to Mr. Joseph Ratner, of Columbia University, and a teacher in the Department of Philosophy at the College of the City of New York, for research in ethics. The Dunning Scholarship, open on this occasion to prospective candidates for the degree of Ph.D., has been awarded to Mr. Lawrence St. Clair Broughall, of University College, London, for research in physics. A Dominion and Colonial Exhibition has been awarded to Mr. J. B. Williams, of McGill University, Montreal.

LEEDS.—Mr. J. R. R. Tolkien has been appointed professor of English Language. He has been Reader in English Language in the University since 1920, and has held several teaching and examining posts at Oxford and elsewhere. The institution, in the English Department of the University, of a separate Chair of English Language, is in accordance with the constitution of corresponding schools at Oxford, Cambridge, Liverpool, Manchester, and elsewhere; and indeed it restores the position which at one time obtained also at Leeds.

Dr. C. E. Gough has been appointed to the Chair of German at the University, which has been in abeyance since 1916.

Dr. S. Brodetsky has been elected the first occupant of the Chair of Applied Mathematics. He graduated as Senior Wrangler at Trinity College, Cambridge, in 1908, held the Isaac Newton Studentship for research in Mathematical Astronomy, and thereafter proceeded to the degree of Doctor of Philosophy at Leipzig. On returning to this country, he joined the mathematical staff of Bristol University in 1914, and came to Leeds in 1919 as Reader in Applied Mathematics. Prof. Brodetsky has produced a long series of papers on many branches of Applied Mathematics, and has devoted special attention to aerodynamics.

LONDON.—Dr. A. W. M. Ellis has been appointed as from October 1, 1924, to the University Chair of Medicine tenable at the London Hospital Medical College.

Dr. E. V. Appleton has been appointed as from August 1, 1924, to the Wheatstone Chair of Physics tenable at King's College. Since 1919 he has been supervisor in physics and mineralogy at St. John's College, Cambridge, of which he is a fellow, and demonstrator and lecturer in the Cavendish Laboratory.

The following doctorates have been awarded, the thesis in each case following the name of the candidate:—*Ph.D.* (*Science*): Mr. J. F. Congdon (King's College), "The Kinetic Energy of the Electrons emitted from a Hot Tungsten Filament in an Atmosphere of (*a*) Argon, (*b*) Hydrogen"; Mr. J. W. C. Crawford (Battersea Polytechnic), "Experiments on the Synthesis of Carnitine"; Mr. A. T. Fuller (Battersea Polytechnic), "Terpincol: its Resolution and Optical Properties, with a Description of some of its Derivatives"; Mr. V. G. Jolly (University College), "Platinocyanides"; Mr. M. A. Matthews (Sir John Cass Technical Institute), "Some Anthracene Derivatives"; Clara Agnes Pratt (Imperial College—Royal College of Science), "Growth Conditions of Fungi"; Mr. H. E. M. Priston (Battersea Polytechnic), "The Alcohols of the Hydroaromatic and Terpene Series: (*a*) Fenchone and the Fenchyl Alcohols, (*b*) The Esters of Borneol and Isoborneol"; Mr. E. J. Weeks (Sir John Cass Technical Institute), "Hydrogen Overpotentials in Alkaline and Neutral

olutions"; Mr. W. Clark, "On the Light Sensitivity f Photographic Emulsions"; Adela Gwendolyn rith (University College, Reading), "A Monograph n White Clover (*Trifolium repens*, L.)"; Mr. P. ewis-Dale, "An Investigation into the Nature of ne Compounds occurring in the Liquid obtained hen Oil Gas is submitted to Pressure, with Sugges- ons as to the possible Utilisation of the Liquid"; Ir. J. N. Sugden (Imperial College—Royal College f Science), "Hydration of Electrolytes and Non- lectrolytes in Aqueous Solution."

MANCHESTER.—The Council has accepted an offer om the brothers and sisters of the late Mr. Philip uckle, a former student of the University, for the ndowment, in his memory, of a scholarship in some anch of Agriculture or Zoology.

The following appointments have been made: ssociate professor of applied mathematics (for ne year), Dr. T. M. Cherry; Assistant lecturer in ngineering, Mr. J. B. M. Hay; Demonstrator in uman physiology, Miss Hilda Linford; Demonstrator n experimental physiology, Mr. E. Nevill Willmer.

SHEFFIELD.—Lord Bearsted has made a gift of 0,000*l.* to the department of metallurgy for the ncouragement of study and research.

APPLICATIONS are invited for the professorship of athology in the University of Melbourne. They hould reach the Agent-General for Victoria, Mel- ourne Place, Strand, W.C.2, by September 20 at atest. Particulars of the post may be obtained from he Agent-General.

IN the report for 1923 of the University of Adelaide, t is announced that the original University Act, which rovides that a subsidy of 5 per cent. up to 10,000*l.* .a. shall be paid by the Government on all endow- nents by private benefactors, has been amended by aising that limit to 20,000*l.* p.a., thus encouraging urther donations. The Council has agreed to assist he Medical Sciences Club in meeting the expense of ublishing a journal of experimental biology and nedical science, which is to serve as a medium for naking known the results of researches carried on in his and other universities. Work conducted in onnexion with the University's Animal Products Research Foundation included a comparison of the rowth of animals initially below the average weight vith that of animals initially above the average. The ubilee of the University is to be celebrated in 1926.

COMPLETE reform of the preparatory school urriculum seems yet a long way off. The Board of Education exercises no control over any of these chools, and, with one or two exceptions, is not nvited to express an opinion on their efficiency. Preparatory school headmasters form a close corpora- ion influenced mainly by the requirements of the Common Entrance Examination, upon the results of which scholarships to the public schools are awarded. In most preparatory schools science is regarded as an expensive luxury which brings no adequate return in the way of "successes." There are, however, a few progressive headmasters who, greatly daring, put the cause of education first. It is interesting to note that Mr. Seymour Bryant, St. Piran's, Maidenhead, has recently added a new block containing an engineering shop and drawing office, two new well- equipped dark rooms, wireless room, technical library, and music rooms. The list savours of pleasure as well as business, but this is a characteristic of a school in which the tradition of Sanderson of Oundle is followed.

Early Science at the Royal Society.

August 10, 1664. The secretary presented the society from Mr. Beal with a box full of several stones, by which the latter conceived it might be seen what is the process of the plastic spirit in shaping perfect cockles, muscles, scollops, headless serpents, fishes, thunder-stones, etc. Then was begun to be read Mr. Beal's annexed discourse relating to these stones, the rest being referred to another meeting, because Mr. Birchinsha was without, expecting to be called in, for the prosecution of the experiments with the monochord.—

Ordered—That Dr Wilkins be desired to speak to the lord Berkley, that he would please, in the name of the Royal Society, to move the committee of the company for the East Indies, that, by their interest in these parts, they would procure such answers, as may satisfy the inquiries to be sent to them; as also such particulars of the productions and curiosities of nature, as shall be specified unto them, and such others, as those parts do afford, and they by their industry can inquire for the use of the said society. Moreover, to write . . . to take special care of the transport of such things.

August 13, 1662. It was voted, That the president attended by the council, and as many of the society as can be obtained, should wait upon the King, after his coming from Hampton-Court to London, to give him humble thanks for his grace & favour: and that in the meantime the president should acquaint his majesty with their intention: and that afterwards the lord chancellor be thanked likewise, as also Sir Robert Moray, for his concern and care in promoting the constitution of the society into a corporation.

August 14, 1686. A letter was read describing the manner of transporting the great globes made for the cardinal d'Estrees by father Coronelli, designed to be presented to the French King; which manner was, that the large carts, in which they were to be carried, were placed upon low wheels, with four axle-trees, that so the wheels might be changed, at the turning of a corner, without altering the position of the case.

August 15, 1666. A letter from Dr Wallis to Mr. Oldenburg, dated at Oxford, was read, importing that whereas he had used to observe in his baroscope, that the sun-shining made the quicksilver to rise, in which the observations of others had concurred; he had this summer in the hot time of June, July and August observed the mercury constantly to rise in the night and to fall in the day. The President affirmed, that he had generally observed the contrary in his baroscope.—

The contrivance for the experiment appointed to shew, that the circular pendulum was made of two strait lines crossing one another, being fitted, as was suggested at the preceding meeting, it appeared, that the motion from the one end of the greater diameter of the circular pendulum to the same end again was equal to two vibrations of the strait line pendulum, equal in length to the former, and moving in the same plane.

August 16, 1686. A note from Mons. Justel was read, giving an account, that a french ship having lately been at the Cape of Good Hope, had been informed by the Dutch there of an expedition, which they had made towards the tropic of Capricorn; and that they had there found a nation, which answered their violins with thirty instruments, and among the rest with one, that was a sort of flute, which was made with a slit instead of holes, and a ferrel case that runs up and down upon it, according to the tone intended by it.

Societies and Academies.

LONDON.

Royal Meteorological Society, July 18 (meeting at the Rothamsted Experimental Station, Harpenden).—Mr. C. J. P. Cave, president, in the chair.—R. A. **Fisher**: Adaptation of variety to climate. One of the main problems attacked by the statistical laboratory at Rothamsted in recent years has been to ascertain numerically the effect of weather on the yield of farm crops. The Rothamsted data give the yield of wheat on thirteen plots which have been under uniform manurial treatment since 1851, and rain records from a large gauge set up in 1853. From these series of values it has been possible to evaluate the actual gain or loss of each consequent upon an additional inch of rain at any time during the harvest year. The work has involved a detailed analysis of the distribution of rainfall through the year for each year since 1853, some of the results of which are of interest. The total rainfall fluctuates greatly from year to year, but there is some evidence that the fluctuations are not at haphazard, but that at two periods centred about 1879 and 1914 there has been a prolonged spell of significantly increased rainfall. On the other hand, one feature of the rainfall distribution has shown a steady and apparently uniform change throughout the 70 years. This involves increasingly wet Decembers, and perhaps drier weather in spring and autumn. Data on this point from other stations would be of great interest.—W. B. **Haines**: A comparison of three different types of radiation recorder. This paper deals with a comparison of the readings taken at Rothamsted with three types of radiation recorder. The first of these is a recorder of the Callendar pattern, depending upon the difference in temperature between a black and a bright resistance exposed to the sky. These readings are taken as standard. The second instrument (Wilson integrator) reads the amount of alcohol or other volatile liquid which distils from a bulb exposed to the radiation into a similar shielded bulb. The third set of data is the record of hours of bright sunshine from the widely-used Campbell-Stokes apparatus. Reference is also made to a fourth set of data, that given by an evaporimeter of the porous candle type, since the readings of this instrument are correlated to the amount of radiation. A diagram made by plotting the data to suitably adjusted units brings out the following points:—(1) The alcohol integrator gives readings much too low during the winter months. The readings could be correlated for the effect of temperature upon the vapour pressure of alcohol, but there is a large random error which makes it impracticable to advance a correction formula to deduce the true radiation. (2) The hours of bright sunshine should be corrected by a factor depending upon the time of day and year (*i.e.* upon the sun's altitude). A formula deduced by Ångström from the Stockholm data, for calculating total radiation from hours of bright sunshine, is examined and found fairly satisfactory for the Rothamsted data. It is concluded that such a formula, based upon the data at one station, could with due caution be adopted for another station.

PARIS.

Academy of Sciences, June 30.—M. Guillaume Bigourdan in the chair.—A. **Desgrez**, H. **Bierry**, and L. **Lescœur**: Relation between the variations of P_H of waters containing hydrogen sulphide and their transformations when exposed to the air. The changes observed are due to two phenomena, oxidation of the sulphur causing a reduction in the P_H, and loss of carbon dioxide producing a rise in P_H.—**Recoura**: The action of acetic acid on hydrated metallic salts. Acetylated salts. Powdered crystallised copper sulphate, $CuSO_4, 5H_2O$, treated with large excess of acetic anhydride loses rapidly four molecules of the water. The fifth molecule fixes only molecule of the anhydride, and it has been proved that acetic acid is not formed. The compound produced is $CuSO_4 . H_2O . [(C_2H_3O)_2O]$. The sulphates of nickel and magnesium form similar compounds.—Alfred **Rosenblatt**: Algebraic varieties of three dimensions, the species of which satisfy the inequality $P_g \leqq (p_g - p_a - 3)$.—R. H. **Germay**: The elimination of the parameters in Cauchy's method and characteristics for the integration of partial differential equations of the first order.—Georges **Giraud**: Two formulæ applicable to the numerical calculation of integrals.—Jacques **Chokhate**: The polynomials of Tchebycheff.—Armand **Cahen**: Classification of the new continued fractions dependent on an operation $R(z)$ to one unit in excess.—E. **Gau**: Condition that a surface may be ruled by deformation.——**Gros**: Finite bending of a circular ring compressed diametrically.—Paul **Dumanois**: Experimental results on increase of compression in aviation motors. In an earlier communication, some results were theoretically deduced concerning the increased explosion pressures and thermal efficiencies of internal combustion motors when an anti-knocking compound such as lead tetraethyl, was employed. In the present paper experiments are described which confirm the theoretical conclusions. Experiments were also made to determine whether the temperature developed at the base of the pistons or at the escape valves were so high as to endanger the low melting material now employed.—Louis **Breguet**: The yield of the propulsion of birds by the motions of the wings.—Louis **Roy**: The fundamental equations of electrodynamics of continuous media in motion.—Maurice **Curie**: The photo-electric and phosphogenic effect.—L. **Riéty**: The electromotive force of filtration.—Charles **Henry**: The calculation of heats of formation and the interpretation of some exceptions to the law of maximum work.—J. J. van **Laar**: The vapour pressure of solid carbon. In a recent communication Wertenstein and Jedrzejewski have given an expression for the vapour pressure of carbon making use of Langmuir's method (evaporation in vacuum) and the Knudsen-Langmuir formula. This leads to 5050° C. (absolute) as the boiling-point of carbon. By an independent method the author arrives at 5010° C. (abs.) for the same constant. The figure 4200° C. (abs.) deduced from the measurements of Lummer and of Mlle. Kohn with the positive crater of the arc is certainly too low.—Francis **Perrin**: The role of viscosity in fluorescence phenomena.——**Bogitch**: The oxidation of chromite and the preparation of chromates. Experiments on heating chromite with various mixtures of lime and sodium carbonate, calcium and sodium carbonates, lime and common salt, lime and sodium sulphate. The influence of temperature and duration of heating were also studied.—P. **Lebeau**: The thermal fractionation of the gaseous products of the pyrogenic decomposition of some definite compounds. The author has shown that by submitting coal to progressively increasing temperatures, the curve showing the relation between gas yield and temperature is definite and constant for a given fuel. The same method has now been applied to definite compounds (starch, sugar, glucose, casein). The results appear to indicate that the method may be of value in studying organic compounds of high molecular weight.—Ch. **Courtot** and R. **Geoffroy**: The

phonation of fluorene. — MM. **Maurain, Eblé, brouste, Mouronval,** and **Escher-Desrivières**: The opagation of seismic waves in the neighbourhood of e origin. Experiments made with seismographs stalled at La Courtine, Felletin, and Ussel, recording e four experimental explosions at La Courtine.— **Diénert**: Subterranean hydrology. Details of chnique relating to the use of fluorescin and other es in tracing the path of underground waters.— dislas **Smolik**: The influence of heat on the total rface offered by the elements of the soil.—L. M. tancès: What is a hæmohistoblast?—A. **Rochon-avigneaud**: Visual lines of the central fovea (in-pendent vision) and the lateral fovea (associated sion) in the kestrel.— —— **de Luna**: The presence an accessory ovary in *Drosophila melanogaster*.— **Lecaillon**: The new races or varieties which can obtained by the method of crossing in the silkworm. (Mlle.) Lucienne **Dehorne**: Remarks on the hippia of *Daphnis longispina*.—W. **Mestrezat** and **Janet**: The dispersion of the electrolytic colloids the protoplasm in relation with the mineral trition of the cell.—Maurice **Piettre** and Clément **oéland**: Trimyristine, the glyceride of milk.—S. **utermilch**: Normal and artificial hæmolysins.

July 7.—M. Guillaume Bigourdan in the chair. H. **Deslandres**: The extension to some line spectra a property already recognised in several band ectra.—Maurice **de Broglie** and A. **Dauvillier**: omplementary researches on the Compton effect. L. **Lumière**, A. **Lumière**, and A. **Seyewetz**: Con-ibution to the study of the latent photographic nage. In experiments on the latent photo-raphic image after fixing, a developer consisting paraphenylene diamine and silver sulphite acting r 48 hours showed a gradual production of particles, hich, under a magnification of 2300 diameters, roved to be hexagonal crystals. These crystals were ot obtained when the developer was silver sulphite issolved in sodium sulphite with addition of formal-ehyde, but if a plate after exposure, fixing, and ashing were treated with an ordinary organic de-eloper, such as diamidophenol, subsequent treat-ent with the formaldehyde-sulphite of silver both eveloped the crystals.—B. **Berloty** was elected a orrespondent of the Academy for the section of eography and navigation in the place of the late lie Colin.—Marcel **Légaut**: Systems of points and he theory of skew algebraical curves.—A. **Demoulin**: urfaces of the Lie quadrics have only two char-cteristic points.—Paul **Mentré**: The projective defor-nation of certain congruences of straight lines.—Rolf **Nevanlinna**: The exceptional values of meromorph unctions.—Pierre **Jolibois** and Georges **Normand**: he decomposition of lead tetra-ethyl and its applica-ion to internal combustion motors. Pure lead tetra-thyl is decomposed at 400°, producing finely divided ead. In the cylinder of an internal combustion notor, lead tetra-ethyl would be decomposed at all ocally heated points covering these with a layer of netallic lead, thus reducing the curvature of any harp points tending to become centres of auto-xplosion.—Pierre **Idrac**: Contributions to the study f the flight of the albatross. An automatic kine-natographic apparatus was utilised in this work: it s concluded that, contrary to all hovering birds reviously studied, the albatross does not utilise scending air currents.—Alfred **Lartigue**: The co-rdination of the thermodynamical properties of water.—André **Marcelin**: Extension of the applica-ion of the gas law to superficial solutions.—L. **Vegard**: The luminous spectra of solid nitrogen and heir application to the aurora borealis and to the diffused light of the sky at night. It is shown that the aurora is probably due to the action of the kathode rays acting upon small crystals of solid nitrogen.— G. **Reboul** and **Bodin**: A new method of production of radiations in the region between the ultra-violet rays and the X-rays. Pastilles of various metallic salts are placed between two electrodes connected to a battery of small secondary cells, the fall of potential across the pastille being variable from 90 to 2430 volts. The radiation emitted is easily absorbed, capable of ionising gases, and has a wave-length between the ultra-violet and the X-rays.—Louis **de Broglie**: The general definition of the correspondence between wave and motion.— — **Lemarchand**: Equilibrium in saline double decompositions in aqueous solution.—L. **Chassevent**: The thermal phenomena which accompany the setting of plaster of Paris.—A. **Boutaric** and Mlle G. **Perreau**: A protection effect of suspensions realised by the addition of electrolytes in quantities too small to effect flocculation.—P. **Job**: The electrometric study of the hydrolysis of salts.—André **Job** and Guy **Emschwiller**: The photolysis of the organic iodides. The photochemical limit and the linkage energies. Pure ethyl iodide, in a closed system free from oxygen, on exposure to light gives free iodine and a mixture of ethylene (53 per cent.), ethane (36 per cent.), butane (6 per cent.), and hydrogen (5 per cent.). When a tube of ethyl iodide is exposed to the arc spectrum, the reaction commences only for wave-lengths shorter than 0·41 μ.—R. **Locquin** and L. **Leers**: Some new pinacolines.—Max and Michel **Polonovski**: Tautomerism of eserine.—Ph. **Négris**: The variation of composition of lavas and the temperature of the pyrosphere.—J. **Thoulet**: Local studies of the circulation of the water in the Atlantic Ocean.—L. **Petitjean**: The application of frontology to the Sahara depressions.—Filippo **Eredia**: The secondary depression of the Adriatic Sea.—Jules **Wolff**: New observations on the loss of the germinating power in the seeds of orchids.—A. **Sartory** and R. **Sartory**: The action of potassium bichromate and copper bichromate on the growth of *Phytophtora infestans*. The copper salt acts more powerfully than the potassium salt in retarding the growth of this organism.—A. **Goris**: The chemical composition of the green fruit of the vanilla and the mode of formation of the perfume of vanilla. —A. **Demolon** and Mlle V. **Dupont**: Some characters of the peat from the chalk valleys of the north of France.—Ch. **Brioux**: Saturation in the soil of sulphuric acid utilised for the destruction of weeds. After this treatment, soils originally acid or containing only small amounts of lime should be limed, or the soil will be left too acid for plant growth.—Louis **Lapicque**: The theory of latent addition.—Boris **Ephrussi**: The segmentation velocities of the egg of the sea-urchin.—F. **Vlès** and A. **de Coulon**: The relations between the state of the organism and the physico-chemical properties of muscular substances. —Jules **Auclair**: The probable cause of the natural immunity of birds towards human tuberculosis and its application to the digestion of the Koch bacillus in the organism of the guinea-pig. A substance has been extracted from the organism of the pigeon, chicken, duck, goose, and turkey which, as extracted, is without action on the Koch bacillus. Under well-defined conditions this substance can be converted into another capable of digesting the tubercle bacillus. No tuberculosis developed in guinea-pigs, if this substance and the Koch bacillus were injected together. No details of the method of extraction, nature of the substance or mode of after-treatment are given.— L. **Hugounenq** and J. **Loiseleur**: The catalytic action exercised by some colloids, more particularly by glycogen, in the hydrolysis of the albumens.

CAPE TOWN.

Royal Society of South Africa, May 21.—Dr. A. Ogg, president, in the chair.—R. F. **Lawrence**: South African spiders. Several genera of South African Thomisidæ illustrate imitations of the calyx, leaves and leaf-axils of flowers and the stems of reeds and grasses. Runciniopsis is much flattened and lies pressed against the stems of grasses, while the straw-coloured form Monoeses has the abdomen elongated into a long cylindrical caudiform process and escapes observation by remaining motionless amongst grass or thin reeds.—F. G. **Cawston**: The smaller South African shells that harbour Cercariæ.—F. E. **Fritsch** and Florence **Rich**: Contributions to our knowledge of the Freshwater Algæ of Africa, V. On a deposit of diatomaceous earth from Ermelo, Transvaal. This deposit occurs as a pan, about half a mile long and 440 yards wide, on the farm Bank-Plaats, and is still being formed. During the wet season, water percolates through the deposit, and living diatoms are found on its surface; in the dry season these mostly die off, and their siliceous valves form the deposit. Seventeen species of diatoms occur in it; one of these is new, and several new varieties are also described and figured.

MELBOURNE.

Royal Society of Victoria, March 13.—Prof. T. H. Laby in the chair.—A. M. **Lea**: On some new Australian Chrysomelidæ.—F. **Chapman** and F. A. **Singleton**: A revision of the Kainozoic species of Glycymeris in Southern Australia. Three new species are here described, namely, *G. gunyoungensis* (Balcombian and Janjukian), *G. ornithopetra* (Janjukian), and *G. planiuscula* (Kalimnan and Werrikooian). An example of the type referred by McCoy to "*Pectunculus*" *laticostatus* shows that two species were represented. The species described by Johnston as "*Pectunculus*" *maccoyi*, from Table Cape, is apparently confined to that locality, and all Victorian records under that name are here referred to other Victorian species. On broad lines the phylogeny of the group in two main series can be traced, linking the early Kainozoic with the living species.—H. **Ashton**: Notes on the Gippsland hairy cicada, *Tittigarcta crinita*, Dist. This insect, unlike the other Cicadidæ, is probably nocturnal, as it flew late in the evening and early in the morning, and was not seen during the day, hiding under bark. The species is not so uncommon as the small series in the various museums would suggest, as on the evidence of the nymphal cases very many must emerge during the season. The specimens were caught close around the Hotel Kosciusko, and are the first recorded from New South Wales.—G. F. **Hill**: Notes on Australian mosquitoes, with descriptions of their early stages.—H. W. **Wilson**: Studies on the transpiration of some Australian plants, with notes on the structure of their leaves. So long as the available water supply was adequate, the transpiration rate increased with the temperature to the limit of the transpiring power of the plant and increased very rapidly when the temperature rose above normal. The highest transpiration rates recorded in grams per sq. metre per hour for the two hottest days of observation were:—*Eucalyptus botryoides*, 750 gm. between 12 and 2 P.M.; *E. cladocalyx*, 640 gm. between 12 and 2 P.M.; *Casuarina Luehmanni*, 525 gm. between 2 and 3 P.M. Strong wind increased the transpiration of such plants as *E. cladocalyx* and *Casuarina Luehmanni*. The acacias were affected very little, while in other species the transpiration was quite disorganised. Stomata were studied in their relations to transpiration. The number per sq. mm. of transpiring surface var *Hakea gibbosa* with 70, and *Myoporum insulare* 80 had the lowest record, while *Casuarina Luehm* with 500, *Eugenia Smithii* with 540, and *Ver Dieffenbachii* with 610 had the highest ave records. The highest records of stomata 1030, 970, and 960 per. sq. mm. on some juv leaves of *Eucalyptus globulus* and 740 on some le of *E. cladocalyx*. The size of the stomata v from 52 × 36 microns (outside measurements *Hakea gibbosa*, and 70 × 65 microns in the adul *alpina*, to 18 × 16 microns on the juvenile leav *E. maculata* var. *citridora*. The so-called xerop plants of Australia are provided with a high ave number of stomata which enables their transpir rate to respond quickly to changes of tempera and water supply, and they are well protecte their tough outer coverings, in some cases assiste glands, from injurious loss of water.

SYDNEY.

Linnean Society of New South Wales, April Mr. R. H. Cambage, president, in the cha W. F. **Blakely**: The Loranthaceæ of Australia (P Six species were described as new.—G. H. **Cunning** A critical revision of the Australian and New Ze species of the genus Secotium. Sixteen specie discussed, fourteen of them being confine Australasia. Five species are described as new **Brough**: Studies in the Epacridaceæ. i. The history of *Styphelia longifolia* (R.Br.). An exp tion of the structure and mechanism of dehiscen the anther is given, and megasporogenesis is descri the micropylar megaspore functions, in place o usual chalazal one. All three non-functional n spores persist in an active state until endos formation is almost completed. This phenom has not previously been recorded in the life-hi of the Angiosperm. The persistence of the functional megaspores evidently represents th tention of an ancestral condition, but the presen function seems to be haustorial.—Marguerite **He** A monograph of the freshwater Entomostraca of South Wales. Pt. iv. Phyllopoda. Nineteen sp are given, six of which are described as new, three others are recorded for the first time from South Wales and one from Australia.

Supplement to NATURE

No. 2858 AUGUST 9, 1924

Prevention of Disease.[1]

By Major-General Sir DAVID BRUCE, K.C.B., F.R.S., A.M.S., President of the British Association.

THIS is the fourth time the British Association for the Advancement of Science has met in Canada rst in 1884 in Montreal, in this city in 1897, and in nnipeg in 1909. The addresses given on these asions dealt with the advancement of knowledge in hæology and physics. It is now my privilege, as a mber of the medical profession, to address you on advances made during the same period in our owledge of disease and our means of coping with l preventing it.

An address on the prevention of disease at first sight es not promise to be a very pleasant subject, but, er all, it is a humane subject, and also a most im- rtant subject, as few things can conduce more to man happiness and human efficiency than the ad- ncement of knowledge in the prevention of disease. ink for a moment of the enormous loss of power in community through sickness. Some little time ago e English Minister of Health, when emphasising the portance of preventive work, said that upwards of ,000,000 weeks of work were lost every year through kness, among insured workers in England. In other rds, the equivalent of the work of 375,000 people r the whole year had been lost to the State. When that is added the corresponding figure for the non- sured population you get some idea of the importance preventive work.

Another way of estimating the value of prevention in terms of dollars, or pounds, shillings, and pence, nd it has lately been calculated that the direct loss England and Wales from sickness and disability mounts to at least 150,000,000*l.* a year. In the nited States, with a much larger population, the loss put down at 600,000,000*l.*

Another reason why this is an important subject is hat medicine in the future must change its strategy, nd instead of awaiting attack must assume the ffensive. Instead of remaining quietly in the dressing tations and field hospitals waiting for the wounded to our in, the scientific services must be well forward in he enemy's country, destroying lines of communica- ion, aerodromes, munition factories, and poison-gas entres, so that the main body of the army may march orward in safety.

It must no longer be said that the man was so sick he had to send for the doctor. The medical practitioner of the future must frequently examine the man while he is apparently well, in order to detect any incipient departure from the normal, and to teach and urge modes of living conformable to the laws of personal health, and the Public Health authorities must see to it that the man's environment is in accordance with scientific teaching. It may be a long time before the change is widely accepted, but already enormous advances have been effected, and it only depends on the intelligence and education of the populations how rapid the future progress will be. Public opinion must be educated to recognise that most diseases are preventable and to say with King Edward VII., "If preventable, why not prevented?"

To our forefathers disease appeared as the work of evil spirits or magicians, or as a visitation of Providence to punish the individual or the community for their sins. It is not my purpose to give a detailed account of the first strivings after a better knowledge of the causes of disease, but it may be said the new era began some few hundred years ago, when it was recognised that certain diseases were contagious. For a long time it was held that this contagion or infection was due to some chemical substance passing from the sick to the healthy, and acting like a ferment; and then, about the middle of last century, the idea gradually grew that microscopic creatures might be the cause.

About this time it had been discovered that the fermentation of grape juice was caused by a living cell and that certain contagious skin-diseases were associated with living fungi. Things were in this position when there appeared on the scene a man whose genius was destined to change the whole aspect of medicine; a man destined to take medicine out of the region of vague speculation and empiricism, and set its feet firmly on new ground as an experimental biological science. I mean the Frenchman, Louis Pasteur. It is from him we date the beginning of the intelligent, purposive prevention of disease. It was he who established the germ theory, and later pointed the way to the immunisation of man and animals, which has since proved so fruitful in measures for the prevention or stamping out of infectious diseases. I need not discuss his life and work further. His name is a household

[1] Inaugural address delivered to the British Association at Toronto on August 6.

word among all educated and civilised peoples. Every great city should put up a statue to him, to remind the rising generations of one of the greatest benefactors of the human race.

What the change in medicine has been is put into eloquent language by Sir Clifford Allbutt: "At this moment it is revealed that medicine has come to a new birth. What is, then, this new birth, this revolution in medicine? It is nothing less than its enlargement from an art of observation and empiricism to an applied science founded upon research; from a craft of tradition and sagacity to an applied science of analysis and law; from a descriptive code of surface phenomena to the discovery of deeper affinities; from a set of rules and axioms of quality to measurements of quantity."

With one notable exception, the medical profession were not quick to see that Pasteur's discoveries of the nature of fermentation and putrefaction had a message for them. This exception was Joseph Lister, who had been for some years endeavouring to comprehend the cause of sepsis and suppuration, which commonly followed every surgical operation and most serious injuries involving a breach of the skin. When, in 1865, Lister read Pasteur's communication upon fermentation, the bearing of the discovery on the problems which had so earnestly engaged his attention was apparent to him. He inferred that suppuration and hospital gangrene, the causes of which had so far baffled his imagination, were due to microbes introduced from the outside world, from the air, and by instruments and hands of the operator. Remember, this was years before the microbial causation of any disease was established.

To test the correctness of his inference, Lister proceeded to submit all instruments, ligatures, materials for dressings, and everything that was to come directly or indirectly into contact with the wound, the hands of the operator, and the skin of the patient, to treatment with chemical disinfectants. The satisfactory results which followed this practice astonished even Lister, and he spent the rest of his active life in improving and simplifying technical methods of preventing the ingress of microbes to wounds, and in convincing his professional brethren of the truth of the conclusions based on this work of Pasteur.

Infectious Diseases—(A) Bacterial.

As soon as it was recognised that infectious diseases are caused by living germs, a wave of enthusiasm swept through the medical world, and it was not long before the causation of many of the most important of them was discovered. I need not give a full list of these, but at or round about the time of the first meeting of the British Association in Canada the micro-organisms of tuberculosis, typhoid fever, Malta fever, cholera, malaria, diphtheria, tetanus, and others had b discovered and described.

But it must not be assumed from what has been s that all the most important diseases are caused living germs. Many of the ills that afflict mankind due to quite other causes—alcoholism, for exam or the deficiency diseases, due to the absence deficiency in our diet of some substance essential proper growth and development. Rickets, one of greatest scourges of industrial communities, is mai a deficiency disease. It is reported that as many 50 per cent. of the children in the slums of some of big cities suffer from the effects of this disease. Th again, there is the whole series of diseases or conditi due to defective or excessive action of our own inter glands. Added to these, and perhaps the great scourge of all, there is the immense amount of chro ill-health and actual disease caused or promoted by unhealthy conditions found in our large cities, due bad housing and overcrowding—the so-called disea of environment.

Malta Fever.

To return to the infectious diseases. After the livi germs or parasites causing them had been isolated, t process of prevention was soon begun. The metho employed were varied, and I may illustrate one of t simplest by relating briefly the history of the preventi of Malta fever, with which I was myself, to so extent, associated. Malta fever is really a widespre disease, although it is called by a local name. It found all round the Mediterranean, throughout Afri as far south as the Cape Province, in India and Chin and even in some parts of America. It was very pr valent in Malta in the old days, and rendered the isla one of the most unhealthy of all our foreign milita stations. When I arrived in Malta, in 1884, I four that every year, on an average, some 650 soldiers a sailors fell victims to it, and, as each man remained an average 120 days in hospital, this gave the hu total of about 80,000 days of illness per annum fro this fever alone.

The British had held Malta since the beginning last century, and, although much attention had bee given to the fever and its symptoms had been full described, no advance was made towards its preventio until 1887, when the living germ, the *Micrococc melitensis*, causing it was discovered. At this time good deal of work was expended in studying the natur history of the fever and the micrococcus, but all to n purpose. Nothing was discovered to give a clue t any method of prevention. At the Naval Hospit especially everything in the way of prevention wa done that could be thought of: the water supply an drainage were thoroughly tested, the walls were scrape and every corner rounded off where dust might li immaculate cleanliness reigned; but all these pre

tions proved useless. Almost every sailor who ıe into the hospital even for the most trivial com- ınt took Malta fever, and after a long illness had to invalided to England.

'hings remained in this very unsatisfactory state for enteen years, until 1904, when the Admiralty and r Office, alarmed at the amount of sickness and aliding in the Malta garrison, asked the Royal iety of London to undertake the investigation of fever. This was agreed to, and a Commission was ordingly sent out in the same year and remained at rk until 1906. During the first year every likely of approach was tried. A careful study was made to how the micrococcus entered the body, how it left body, its behaviour outside the body, its patho- ıic action on various animals; but still no indication a method of prevention showed itself. Next year, wever, in 1905, the problem of prevention was ved, and that by the merest of accidents.

In the previous year experiments had been made :h the object of finding out if the goat, among other imals, was susceptible to the disease. The goats in lta, which supply all the milk, are very much in idence, as they are driven about in small herds and lked as required at the doors of customers. Several ats had been injected with cultures of the micro- :cus, but, as they showed no rise of temperature or y signs whatever of ill-health, they were put aside being immune or refractory to the disease and thing more was thought about them.

In the spring of 1905, about six months after these periments had been made, Dr. Zammit, a Maltese mber of the Commission, who had kept one or two of ese goats, happened for some reason or other to amine their blood, and found that it clumped or glutinated the micrococcus. This was strange, and emed to show that, although the micrococcus had t caused fever or any signs of illness in the goats, it ust have lived and multiplied in the tissues of these imals in order to have brought about this change in e blood. This observation led to the re-examination the immunity of the goat, when the extraordinary scovery was made that about 50 per cent. of the goats the island were affected by this disease, and that 10 r cent. of them were actually excreting the micro- ccus of Malta fever in their milk. Monkeys fed on ilk from an affected goat, even for one day, almost variably took the disease.

Thus the weak link in the chain of causation had been und. The military authorities struck Maltese milk ut of the dietary, and replaced it by an imported ariety, and from that day to this there has scarcely een a case of Malta fever in the garrison. Malta, om being the most unhealthy of foreign stations, ecame a health resort, and was in fact used as a anatorium during the late War. The disease had been blotted out at a single blow. This, then, is one way of preventing an infectious disease; that is to say, by the discovery of the living germ, the study of its natural history, and so to a means of stopping it reaching its victim, man. This is the best way of prevention: shutting the stable door before the horse is stolen.

Typhoid Fever.

There are, however, other ways of preventing bacterial diseases. Let us take, for example, a method widely used in the prevention of typhoid fever. The fundamental and sound way of attacking this disease is by ordinary hygienic measures, especially a good water supply and good drainage. It is therefore one of the first duties of those in power to see that their people have, in addition to houses with plenty of light and air, a good water supply and a good drainage system, and money cannot be spent to better advantage than in the attainment of these three essentials to health.

When typhoid fever is rife in a community, it means that there is either a contaminated water supply or a faulty drainage system, and the municipal authorities ought to be called to account. In England, owing to improved sanitation, cases of typhoid fever are fifteen times less than they were fifty years ago.

It is not always possible to ensure good hygienic surroundings—for example, among troops on active service. It is therefore legitimate under certain conditions, and especially in time of war, to practise a less sound, a less fundamental, method of prevention, and this second method is known as inoculation or vaccination. In order to understand how this acts, let us consider, for a moment, what takes place in a man's body when he is attacked by the typhoid bacillus. Everybody knows that the bacillus gives rise to poisons or toxins which cause the fever and other symptoms. But the cells and tissues of the man are not passive under the attack. They at once begin to fight against the infection, by forming substances in the blood to neutralise these toxins, hence called antitoxins or anti-bodies, and their function is finally to destroy the invading germs. If the man recovers, he is immune from a further attack by the presence of these antibodies in his blood. He has become immune by passing through an attack of the disease.

This is the foundation of the second way of preventing infectious diseases. Speaking broadly, it means that you subject a man to a mild attack of the fever in order that his blood and tissues will respond to the stimulus by producing antibodies. This method takes its origin and name from that of vaccination against smallpox. Jenner solved that problem by the accidental discovery of vaccinia, a form of smallpox attenuated or weakened by passage through another species of animal. This weakening of the virulence of a micro-

organism by passage through another kind of animal is by no means uncommon in Nature.

Pasteur, following on these lines, conceived the idea of weakening or attenuating the virulence of the living bacilli by artificial means, so as to give rise to a mild attack of the disease, and in this way to render animals immune. This he did with marked success in anthrax and chicken cholera.

The next forward step in this method of preventing disease was made by Haffkine, a pupil of Pasteur, who about the year 1894 produced a vaccine against cholera, and a few years later another against plague. In the course of this work it was discovered that it was not necessary to use living cultures of the bacilli, but that vaccines made up of dead bacilli had much the same effect. This substitution of the dead bacilli for the living was a great advance in the method, being much simpler and much safer.

The next disease to be attacked by this method was typhoid fever. This was initiated by Sir Almroth Wright at the British Army Medical School, and carried out with that investigator's characteristic ability and energy. The method was mainly directed in the first place to lessen the mortality from this disease among our soldiers serving in India. After several years' experience, the mode of inoculation which was finally settled on was to give two injections of dead typhoid bacilli, one of 500 millions, and a second, at an interval of ten days, of a thousand millions.

Now let us see what effect anti-typhoid inoculation has had on the prevention of typhoid fever among our soldiers in the field. In the South African War, at the beginning of the century, before the method had been developed, in an army the average strength of which was only 208,000, there were 58,000 cases of typhoid fever and 8000 deaths. In the Great War, on the Western Front, with an average British strength of one and a quarter millions, there were only 7500 cases and 266 deaths. In other words, there were fewer cases of the disease in this War than there were deaths in the South African.

It is also interesting to learn from French sources that at the beginning of the War the French soldiers were not inoculated, whereas the British were. The result for the first sixteen months was striking. During this time the French had some 96,000 cases, with nearly 12,000 deaths. The British had only 2689 cases and 170 deaths. Afterwards the French soldiers were very thoroughly vaccinated, with the result that their immunity eventually became as striking as our own.

What the number of cases and death-rate from typhoid fever might have been in the huge armies fighting on the different fronts had it not been for this preventive inoculation it is impossible to say, but undoubtedly the suffering and loss of life would have been enormous. I may therefore conclude this account of anti-typhoid inoculation by saying that it certa constituted one of the greatest triumphs in the prev tion of disease during the recent War.

Tetanus and Diphtheria.

I shall now pass on to consider a third method preventing bacterial diseases which has also b evolved during the time under review; that is, by injection of specially prepared blood sera. These known as antitoxic sera, and the most familiar examp are anti-tetanic and anti-diphtheritic.

We have seen how the injection of living or de bacilli or their toxins into animals gives rise to t production of antibodies or antitoxins. The blo serum of such animals in virtue of the antibod contained in it can be used to combat disease. I us take in the first place the case of tetanus, ur recently considered to be one of the most fatal maladies, at least 85 per cent. of the cases succumbi As you are aware, anti-tetanic serum is prepared injecting horses with large quantities of tetanus tox When the blood is as full as possible of antibodies, is drawn off and the serum allowed to separate out.

The idea lying behind this third method of p venting disease is to pour in these ready-made an toxins in order to assist the body in its first strug with the invading disease, and give it, as it were, breathing space to prepare its own defences. Natura the immunity produced by these antitoxic sera is o passive nature and of short duration, as compar with that produced by the disease itself, or even the milder form brought about by vaccination inoculation. Anti-typhoid inoculation will protect soldier for, let us say, two years; anti-tetanic ser will protect for only a week or ten days. It is the fore impossible to inoculate a whole army agai tetanus. It is necessary to wait until there is a dan of the disease occurring.

To illustrate this I shall describe briefly the hist of the prevention of tetanus during the Great W When the British Expeditionary Force went over France in August 1914, only a small quantity of an tetanic serum was taken, and that for the purpose treatment rather than prevention. But shortly af the outbreak of hostilities, the number of cases tetanus among the wounded became so alarming th no time was lost in grappling with the danger. La quantities of serum were hurried to the front, a some two months after the beginning of the War it w possible to make an order that every wounded m should receive an injection of anti-tetanic serum soon after he was wounded as possible. Later after further experience had been gained, the sin injection was increased to four, given at intervals o week. This helped the wounded man over the dang ous time, and the results were very successful.

in August and September 1914, before the prolactic injection was given, roughly speaking, nine ten out of every thousand wounded were attacked tetanus, and some 85 per cent. of these died. After anti-tetanic injections had been introduced, the idence fell to little more than one per thousand, the mortality to less than half. To put the matter adly: during the War there were 2500 cases of anus in the British Army, with 550 deaths. If re had been no prophylactic injection of anti-tetanic um, there would probably have been 25,000 cases h 20,000 deaths—a very striking example of the ent development in the prevention of disease.

Another very important and widespread disease, newhat resembling tetanus, is diphtheria, and there no better example of the advance of science in thods of cure and prevention than is found in this ease. Thanks to the work of Klebs and Löffler in early 'eighties and, some years later, to the brilliant earches of Roux and Yersin, the causation and tural history of this disease were very thoroughly cidated. Anti-diphtheritic serum is prepared much the same way as the anti-tetanic. By the repeated ections of gradually increasing doses of the bacilli their toxins, a serum is produced which has a marked rative effect in cases of diphtheria. It is stated that e introduction of anti-diphtheritic serum in 1894 s reduced the death-rate from 40 to 10 per cent., d if used on the first day of the disease to almost *nil*.

The serum is essentially a curative agent and is eful only to a limited extent in prevention. But ely essentially preventive measures in diphtheria ve come into vogue. The procedure employed is bring about an active immunisation by a mixture toxin and antitoxin in individuals who have been own to be susceptible to the disease by what is own as the Schick test. In the United States, a mpaign on these lines has been begun against this sease which promises brilliant results. It is confidently ated that by their new measures there is a possibility robbing diphtheria of all its powers to kill or injure.

The mode of prevention of these diseases—Malta ver, typhoid fever, and tetanus—illustrates the three incipal methods of preventing bacterial diseases: Malta fever, by getting down to bed-rock and pping the disease at its source; in typhoid fever, giving, as it were, a mild attack of the disease, by ccination or inoculation, so as to bring about a eater power of resistance; in tetanus, by pouring antitoxins, already prepared in the serum of another imal, in order that they may neutralise the toxins the invading bacilli as soon as they are formed.

Tuberculosis.

There are other important bacterial diseases, however, which cannot be attacked so simply. For example, there is tuberculosis, a disease distributed over the whole world and one of the greatest scourges of civilised communities. It is a disease which has been known from time immemorial, but it is only within our own time that the bacterial cause has been recognised. I can well remember a day in 1882 when I met a fellow student who had just returned to Edinburgh from Germany. He told me that it had been recently discovered that the disease was really caused by a living germ, the tubercle bacillus. It was difficult at first to believe such a revolutionary idea, but such was the interest and excitement raised that many workers at once took up the study of the subject, and in a short time the truth of Koch's great discovery was fully proved. This was a magnificent example of research work, most admirably, carefully, and completely carried out, and placed Koch at once in the front rank of scientific workers.

Before Koch's discovery a good deal had been done in the way of prevention. Before all things, this disease is a disease of environment. Its birthplace and home is the sunless, ill-ventilated, overcrowded room. The late Prof. Edmund Parkes, Professor of Hygiene at the Army Medical School, reduced to a great extent the incidence of tuberculosis in the British Army by procuring for the soldier more floor-space and more air-space in his barracks. It is related of General von Moltke that when he heard of the death of Parkes he said that every regiment in Europe should parade on the day of his funeral and present arms in honour of one of the greatest friends the soldier ever had.

The prevention of tuberculosis is thus seen to depend fundamentally on the provision of a better environment and the education of the people in physiological living. To attain this in the older civilisations will be a hard task, entailing enormous expenditure of money and energy. In the Report of the Royal Commission on the Housing of the Industrial Population of Scotland in 1917 is described the unsatisfactory sites of houses and villages, insufficient supplies of water, unsatisfactory provision for drainage, the gross overcrowding in the congested industrial towns, occupation of one-room houses by large families, groups of lightless and unventilated houses in the older burghs, clotted masses of slums in the great cities—a terrible picture, the heritage of the age of ignorance, internal strife, and walled towns.

The people of new countries should see to it, and doubtless will see to it, that these old evils are not perpetuated. As Sir Robert Philip, Professor of Tuberculosis in the University of Edinburgh, has eloquently said: "Were it possible to begin afresh the scheme of civilised life, were it possible to undertake anew the creation of cities and the homes of our people, were it possible to place within the recreated dwellings an

understanding race, detuberculisation might be quickly attained. What a magnificent opportunity for the builders of the new cities, the moulders of fresh civilisations, with the grand purpose of 'No tuberculosis.' The architect, the sanitarian, and the citizen would agree in insisting that physiological laws should be paramount, that there should be effective obedience to the larger demands of hygiene in the home, the school, the workshop, the meeting-place and the cow-shed. Mankind was born into air and sunlight: these are his natural heritage. They are more—they are the irreducible conditions of life."

In regard to the tubercle bacillus it is so widespread, so ubiquitous in civilised communities, passing from one infected host to infect another, that it would seem impossible under existing conditions to prevent its spread. At present it is taught, and on what seems good evidence, that the majority of the population of our crowded cities has at one time or another been attacked by this disease. But in every hundred men who die in England, only about ten die of tuberculosis, which shows that a large percentage of the population successfully resists the tubercle bacillus. When this occurs it means that the person attacked possessed powers of resistance which enabled him either to destroy the invading bacilli or deal with them so as to render them harmless.

A point of importance in this connexion is that it has recently been demonstrated that the disease is usually acquired in childhood. The fact is of capital significance, for if the disease is recognised sufficiently early, and the child is placed under good hygienic conditions, there is a very good chance of effective resistance and immunity against a second attack being set up. The present evidence goes to show that the presence of latent tubercle prevents a second invasion. If further outbreaks take place, they would seem to be due to a flaring up of the old latent tubercle rather than to a fresh infection. Metchnikoff studied the question in a remote part of Siberia where the tubercle bacillus was unknown. He states that very many of the young men and women who migrated from this clean country into the big cities died of acute and rapid tuberculosis, on account of not having been exposed to infection in their childhood.

The experience of Colonial troops in the late War is instructive. Thus, in France the Senegalese, who are almost without tuberculosis in their native condition, and were found to be free from tuberculosis on reaching France, developed in large numbers an acute and fatal form of tuberculosis in spite of the hygienic measures enforced by the Army authorities. This raises a curious point. If it were possible for any country to clear itself of the tubercle bacillus, it would appear to be incurring a great risk for an inhabitant to migrate into any neighbouring country. But, in spite of this, it is the duty of medical men to keep in check, as far possible, the ravages of the disease.

The preventive measures against tuberculosis at t present time are, in the first place, improvement in t general hygienic conditions. Thereby individual resi ance—and communal resistance—can be remarkal increased. In the second place, as every case of tub culosis must arise from a previous case, either human bovine, it is very necessary that methods of ea diagnosis, preventive treatment, and segregation of t more infective types should be employed. This is do by the setting up of tuberculosis dispensaries, c committees, sanatoria, hospitals and colonies. Th several elements are combined in the model Tub culosis Scheme which is now universal throughout Gr Britain. In the third place, much can be done anticipate and limit the progress of infection by t use of tuberculin, but caution is required in assessi the claims, sometimes hasty and extravagant, advanc by adventurers in this field of research.

Many other points might be brought forward, b the subject is such a vast one that I must conte myself with directing attention to the importance o sound milk supply. The contamination of our ho herds with tuberculosis is so great that no pains shou be spared to secure a safe milk supply, and I und stand that the city of Toronto is a model in this respe

The result of these methods of prevention agai tuberculosis may be given briefly. Sir Robert Phi writes that in Scotland ten years before Koch's d covery the death-rate from this disease was 404 p 100,000; in 1920 it had fallen to 124 per 100,000, a f of 69·3 per cent. He also points out that the "rec acceleration of rate of reduction which is noticeal in England and Scotland is of arresting interest. Scotland the acceleration of fall in the mortality r likewise arrests attention. Thus, during twenty ye up to 1890, the percentage fall in mortality from forms of tuberculosis was 35, while during twenty ye from 1900 to 1919 the percentage fall was 45."

This is very satisfactory, and has only been arriv at by hard work on the part of medical men, nurs and voluntary workers. Any tuberculosis schem however perfect in theory, will require untiring ener patience, and perseverance to bear fruit. On this si of the Atlantic, in the United States, these an tuberculosis schemes have been pursued with e thusiasm, with the result that Washington in 1920 h a death-rate, from all forms of tuberculosis for 100,0 of the population, of only 85, Chicago 97, and New Yo 126. London in the same year had a death-rate 127, practically the same as New York. Other natio have not been so energetic in preventive measur Vienna having in 1920 a death-rate of 405, and Pa 279 per 100,000 from the same cause.

It is evidently the duty of every nation to take

ns against a disease which exacts such a terrible toll leath, suffering, and inefficiency. If this were done h energy and enthusiasm it is not too much to hope t in a few generations the tubercle bacillus would be ctically brought under control, and with it many er malign influences.

Infectious Diseases—(B) Protozoal.

I shall now pass on to the consideration of the second at group of infectious diseases, the Protozoal, and sider what methods of prevention have been found olicable to them.

The scientific study of the protozoal diseases of man y be said to have begun with the epoch-making covery of the malaria parasites in 1880 by the istrious Frenchman, Laveran; next, in 1893, the covery by Theobald Smith and Kilborne of the cause Texas fever and the part played in its dissemination the cattle-tick; in 1894 the discovery of the trypnosome of nagana and its intermediate insect host te tsetse-fly; in 1898 the working out of the development of the malaria parasite of birds in the mosquito Ronald Ross, greatly aided and abetted in the work Patrick Manson, which led, through the work of Grassi and his fellow-workers in Italy, to the final olution of the malaria problem. A year later the imrtant discovery of the mosquito carrier of yellow ver was made by the American Army Commission, der the directorship of Reed, and in 1903 Leishman nounced his discovery of the protozoal cause of la-azar.

These protozoal diseases are world-wide, like the cterial, but it is in the warmer climates that their ect is most felt. The great plagues of the tropics, ch as malaria, amœbic dysentery, kala-azar, and eeping sickness among men, Texas fever, tsetse-fly sease, and others among domestic animals, are caused minute microscopical animal parasites. Large acts of country have been and are still rendered unhabitable to white settlers by their presence. The bening up of Africa, for example, was rendered difficult the tsetse-fly, before the advent of railways. No oner had an expedition started for the interior than e fly attacked the cattle transport, and before long e expedition had to make its way back as best it uld to its base on the coast. The only way to get to the country was on foot with native porters.

The protozoal diseases of domestic animals have also d to enormous loss in all parts of the world. Texas ver, or red-water, has swept whole countries of their ttle. After the Boer War, South Africa was devastated by the introduction of East Coast fever, nother protozoal disease of cattle closely related to exas fever. How is the prevention of these diseases be brought about? We find that up to the present ttle can be done by way of vaccination or inoculation or by the use of anti-sera as in the bacterial diseases. On studying the natural history of these protozoal parasites, however, it is found that many of them depend on an intermediate insect host for their continued existence, and it is by taking advantage of this characteristic that methods of prevention can be devised. To illustrate this I might cite the classical examples of malaria and yellow fever, but, as these must be familiar to you all, I shall take instead the trypanosome diseases of Africa, the best known of which are sleeping sickness in man and nagana or tsetse-fly disease in the domestic animals.

Nagana or Tsetse-fly Disease.

In 1894, a year after Theobald Smith and Kilborne had published their famous monograph on Texas fever, a severe epidemic among native cattle in the north of Zululand was reported to the Natal Government. The disease was called nagana by the natives, and it is curious that there was no suspicion at the time that it had any connexion with the tsetse-fly. At this time a very enlightened administrator, the late Sir Walter Hely-Hutchinson, was Governor of Natal and Zululand, and it was due to him that the investigation of the cause of the Zululand outbreak was at once undertaken. As I happened to be stationed in Natal at this time I was chosen to undertake the work, and at once started on the long journey, mostly by ox-wagon, to the scene of the outbreak.

On examination of the blood of the nagana cattle, a minute active flagellated protozoal parasite, belonging to the genus Trypanosoma, was discovered, and after many experiments on dogs, horses, and cattle it was decided that in all probability it was the cause of the disease. Trypanosomes had previously been described in the blood of rats and horses in India by Timothy Lewis and Griffith Evans, but nothing was known as to the mode of their transmission from animal to animal.

It seemed as if the discovery of the nagana trypanosome would have ended the investigation in Zululand without any means of preventing the disease being discovered, but another observation made at this time threw more light on the subject. In the low country, between the high ground on which the nagana camp was situated and the sea, there happened to be a so-called "Fly belt." Every schoolboy had read about the tsetse-fly in books of travellers and hunters, especially in those by the most famous of them all, David Livingstone the missionary, and out of curiosity I decided to find out what happened when an animal was bitten by the fly, or, as it was termed, fly-struck. Natives were therefore sent with cattle and dogs into this "fly country," with orders to form a camp and expose the animals to the bites of the fly. This was done, and it was with great surprise that on their

return to the hill the blood of these fly-struck animals was found to contain the same parasite as that found in the nagana cattle.

Nagana and tsetse-fly disease were finally proved to be identical. The tsetse-fly disease was shown to be caused, not, as had been believed, by the poisonous bite of the fly, but by the transference of a protozoal parasite from the fly to the animal in the act of sucking blood. Now the question arose as to where the fly found the parasite. As the tsetse-flies constantly lived among and fed on wild game, such as buffalo and antelope, these animals were suspected. Their blood was examined, and before long it became evident that the wild animals acted as the reservoir of the disease, the trypanosomes living in their blood as harmless parasites. When the tsetse-fly fed on blood containing the trypanosome it became infected, and was capable by its bite of giving rise to a fatal disease in cattle, horses, or dogs; whereas if it fed on a wild animal nothing happened, as the wild game are immune to the disease, much in the same way as the goat is immune to Malta fever.

Now that the natural history of the disease had been so far worked out it was evident that its prevention might be attempted. This can be done in any of three ways: by getting rid of the wild game, the reservoir; or by getting rid of the fly, the vector or carrier; or, lastly, by removing the cattle, horses, and dogs to a safe distance from the "fly country." This work on nagana led later, in 1903, to the discovery of the cause and mode of prevention of sleeping sickness.

Sleeping Sickness.

About the beginning of the century an epidemic of this disease raged round the shores of Lake Victoria in Central Africa. It had been introduced into Uganda from the West Coast, where it had been known for many years as a curious and unaccountable disease. It was observed that although the disease spread in a West African village from man to man apparently by contact, no such thing occurred among natives exiled from their homes. The disease never spread if introduced into native compounds in the West Indies or America, however closely the slaves might be herded together. The disease remained shrouded in mystery, and nothing had been done in the way of prevention, until the matter was taken up by the Royal Society of London in 1902 and a Commission sent out to investigate. It is not necessary to go into details; suffice it to say that after one or two false starts the Commission in 1903 came to the conclusion that the disease was caused, as in nagana, by a species of trypanosome.

The question of the distribution of sleeping sickness in Uganda was then taken up. This disclosed the remarkable fact that the disease was restricted to the numerous islands in the northern part of the lake and to a narrow belt of country skirting the shores of t lake. In no part of Uganda were cases found mo than a few miles from the lake shore. The ne important step in the working out of the etiology w made when it was shown that the distribution of t disease was identical with the distribution of t common tsetse-fly of the country, *Glossina palpal* Where there was no fly there was no sleeping sickne

The problem was now solved. The epidemic cou be stopped either by getting rid of the fly or by r moving the natives out of the fly area. As the destru tion of the fly was impracticable under the circur stances, the second method was decided on. T natives were moved from the islands and lake sho and placed on healthy inland sites, and the epidem which had cost the Protectorate some 200,000 liv speedily came to an end.

This method of preventing disease, by removing m out of the zone of danger, is an extravagant one, a can only be done in exceptional circumstances. Uganda the native population could be easily move but it meant that from about 1910 until the prese day some of the most fertile land in Uganda has be lying derelict, has returned to the primitive jung The War delayed things, of course, but it is only n that the natives are being returned to their old hom on the islands and lake shore, in the hope that the by this time has lost its infectivity.

The other method, by the destruction of the tsets fly, has been carried out successfully in other plac For example, in the island of Principe, off the We Coast of Africa, by destroying the wild animals whi supplied a large part of the food of the fly and clearing the jungle, the tsetse-flies disappeared, and wi them the disease. This is the method employed malaria and yellow fever. It was by destroying t mosquito carrier that Gorgas drove yellow fever o of Havana and, later, both malaria and yellow fev from the Panama Canal zone. Thus through the wo of Manson, Laveran, Ross, Reed, and others has been made possible to deal with these two scourges the tropics, malaria and yellow fever. I include yell fever among the protozoal diseases, although Noguc in 1919 brought forward strong evidence that it caused by a spirochæte.

In regard to yellow fever the victory has been almo won. During the last century this disease, known "yellow jack," devastated the West Indies and Centr and South America. At the present time, thani chiefly to the unremitting efforts of the late Gener Gorgas and the International Health Board of t Rockefeller Foundation, the disease has been driven o of the West Indies and Central America, and on retains a precarious foothold in Colombia and Braz whence it will doubtless be ejected during the ne year or two.

One of the best examples of the prevention of disease the attack made on yellow fever in Rio de Janeiro, capital of Brazil, by the well-known man of science, Oswaldo Cruz, with the result that the annual ths in the city from yellow fever fell from 984 in 2 to 0 in 1909. This brilliant result was brought ut by the destruction of the Stegomyia mosquito, intermediate insect host in yellow fever.

So also in the case of malaria. A dozen years ago, sed on the experience gained by Ross on the West ast of Africa and Ismailia and by Watson in the derated Malay States, the method of prevention by squito control and drainage has been so perfected t the practical blotting out of malaria from a given ality is now merely a matter of expense. A great al of work has been done during the last few years the way of experiment in the United States, and ncent, the President of the Rockefeller Foundation, ely stated that there is evidence that "under normal nditions an average community can practically rid elf of malaria at a *per capita* cost of from 45 cents to per year."

This is an altogether inadequate account of the thods of preventing these highly important protozoal seases. From the few examples given it will be seen at they are most rampant in warm climates, that they e as a rule conveyed from the sick to the healthy by insect intermediary, and that it is by an attack on is insect, be it mosquito, tsetse-fly, or tick, that the st chance of success in prevention lies.

Infectious Diseases—(C) Undetermined Group.

In addition to the bacterial and protozoal infectious seases, there is a third and large class, known as the undetermined group," in which the parasite is either known or doubtful. Many of these undetermined iseases are very common and familiar, such as influenza, measles, scarlet fever, smallpox, typhus fever, rench fever, dengue fever, and sand-fly fever; among nimals, rabies, rinderpest, foot-and-mouth disease, and frican horse-sickness. The theory generally held at resent in regard to most diseases included in this roup is that the living germs causing them are ultramicroscopical, in at least some part of their life history, nd this is strengthened by the fact that many of them lass through porcelain filters, which keep back the mallest of the visible bacteria. Hence the name filter-passers."

Many of these undetermined diseases are highly infectious and appear to infect at a distance through the air, as, for example, in influenza, scarlet fever, and smallpox. In some of them there is no attempt made at prevention, except that the sick are isolated and placed under quarantine for a longer or shorter period. But in others there are well-known methods of prevention even when the virus is quite unknown. The best example is smallpox, the ravages of which have been completely held in check since the memorable discovery of Jenner. As has already been argued, this method of prevention, by inducing a mild or attenuated form of the disease, is at best a clumsy one, and when the natural history of the smallpox virus is better known it may be hoped that a more fundamental method of preventing this disease may be discovered. In the meantime the best means at our disposal is by the use of vaccine lymph, and people should recognise their responsibility to the community if through ignorance or selfishness they refuse to have their children vaccinated.

Another well-known disease with an unknown virus, rabies or hydrophobia, has also, by the genius and intuition of Pasteur, been robbed of many of its terrors. The mortality following bites of rabid animals has fallen from 16 per cent. to less than 1 per cent. But in rabies, when the conditions are favourable, the radical method is to drive the disease altogether out of the country by the careful administration of muzzling and quarantine laws. This was carried out successfully in England at the beginning of the century.

Trench Fever.

There are among the diseases of undetermined origin a few which are slowly emerging from the unknown into the known. One of the most interesting of these is trench fever, which came into great prominence during the War. The history of the investigation of this fever is interesting, and well illustrates the method of studying a disease with a view to its prevention. Before the War trench fever was unknown, though there is some evidence that it had been recognised at an earlier date in Poland and called Wolhynia fever. Be that as it may, it is quite certain that, though it was unknown on the Western Front at the beginning of the War, it is no exaggeration to say that it became one of the most powerful factors in reducing our man-power, probably more than a million cases occurring among the Allies on the Western Front. In 1917 in the Second British Army alone, out of a total of 106,000 admissions to hospital at least 20,000 of the cases were trench fever.

Although this fever has well-marked characteristics of its own, such as a peculiar type of temperature curve, and other symptoms, yet for a long time it was unrecognised as a separate entity, and remained mixed up with other diseases, such as typhoid fever, malaria, and rheumatism. In 1916 MacNee, Renshaw, and Brunt in France made the first definite advance by showing that the blood of trench-fever cases was infective. They succeeded in transferring the disease to healthy men by the injection of the blood. The most careful microscopic examination of the blood corpuscles and lymph failed, however, to reveal any

living germ. Nothing more was done until the following year, when the British War Office took the matter up seriously and formed a committee for the purpose of investigating the disease.

The United States of America, on coming into the War, at once recognised the importance of trench fever, and without delay also undertook its investigation. In October 1917, at the first meeting of the Medical Research Committee of the American Red Cross in Paris, Major R. P. Strong recommended that a research into trench fever should be undertaken. He stated that, after several months' study of the problems relating to the prevention of infectious diseases occurring in the Allied Armies on the Western Front, it became evident that the subject of the method of transmission of trench fever was one of the most important for investigation in connexion with the loss of man-power in the fighting forces.

At the next meeting, in November 1917, this was agreed to, and a Trench Fever Committee, under the chairmanship of Major Strong, was formed. The research was organised, and experiments begun on February 4, 1918. In less than six months the investigation was completed and the report in the hands of the printer. This is a striking example of research work which, if carried out at the beginning of the War instead of at the end, might have saved the Allied Armies hundreds of thousands of cases of disease, which, although never fatal, were often of long duration and led to much invaliding.

The most important result of the work of these two committees was that it was amply proved that the louse, and the louse alone, was responsible for the spreading of the disease. This discovery meant that in a short time trench fever would have disappeared from our armies on the Western Front. Just as the elimination of goat's milk blotted out Malta fever, the elimination of the mosquito malaria and yellow fever, so would the elimination of the louse have completely blotted out trench fever. This method of prevention, by the destruction of the louse, although doubtless requiring careful organisation and energy in carrying out, was shown before the end of the War to be a perfectly practicable proposition, and there can be little doubt that, if the War had lasted much longer, trench fever, like tetanus, would have practically disappeared.

Besides the main discovery from the preventive point of view that the louse is the carrier, there are many other points of interest in the natural history of trench fever. The living germ causing it has never been recognised in the human blood or tissues, probably on account of its extreme minuteness, and its consequent liability to confusion with other small granules. But when the louse sucks blood from a trench-fever case there is apparently a great multiplication and development of the supposed micro-organism. In five to nine days the louse becomes infective, and there is seen in the stomach and intestines enormous numbers of very minute bodies. What the exact nature of these bodies is, is unknown, but there can be little doubt that they are the infecting agents by which the louse passes on the disease. They pass out in countless numbers in the droppings or excreta of the louse, and it is to these bodies in the excreta that infection is due. The louse seldom if ever gives rise to the disease in the act of biting. It is the infective excreta thrown out on the skin which causes the infection. The micro-organisms or so-called Rickettsia bodies contained in the excreta find their way into the blood through abrasions or scratches, and so give rise to the fever.

From what has been said it will be seen that trench fever is an interesting disease. It also explains why it disappears in times of peace. As soon as the War was ended, and our men could leave the trenches and resume their normal habits, the disease disappeared. The louse was eliminated and the trench fever with it.

Typhus Fever.

Another disease of the undetermined group closely related to trench fever and also carried by the louse is typhus fever, one more of the furies following on the heels of war. The French and British Armies escaped this scourge to a great extent, but some of the other countries, such as Serbia, Bulgaria, and Poland, were not so fortunate. It is stated that 120,000 Serbians died of this disease during the War, and it was only after vigorous steps had been taken in sanitary measures directed against the louse that the epidemic was got in hand.

After the long, exhausting Napoleonic wars, with the resulting poverty and destitution, typhus fever was prevalent in Great Britain and Ireland. About the middle of the century the improved economic conditions gradually led to the disappearance of the disease in Britain, although cases still occur in some parts of Ireland.

It is to Nicolle that we owe the advancement in our knowledge of this important disease. His work in Tunis on this subject dates from 1909. He showed that the blood of typhus cases is infective to monkeys, and, most important of all, that the infection takes place through the body louse. Just as in trench fever, the louse becomes infective after some five days, and it has been shown by the late Arthur Bacot of the Lister Institute that the excreta is also infective.

The minute bodies found in the typhus louse are, subject to some differences, very similar to those found in the trench-fever louse, and have been named *Rickettsia prowazeki* by Rocha Lima. What group these bodies belong to is still a matter of discussion. Some consider them to be protozoa, with an ultra-

roscopical stage in man and a developmental stage the louse, while others look on them as minute ms of bacteria. Although there is still some doubt o the pathological significance of these Rickettsia ies, the work of Sargent, Rocha Lima, Arkwright Bacot, Wolbach, Todd and Palfrey has done much establish a causal relationship between them and se two diseases, typhus and trench fever.

From the point of view of prevention, the important at is that the infection is carried by the louse, and in next great war it will be almost as necessary to pare means for the destruction of the lice as of the my.

Rocky Mountain Fever.

A third disease belonging to this interesting little up—Rocky Mountain fever—occurs in certain alities in the United States. It provides another stance of a virus transmitted by an invertebrate host man. As the result of the work of Ricketts and of olbach, the wood-tick, *Dermocentor venustus*, is now cognised as the vector. Rickettsia bodies closely sembling those found in association with typhus and nch-fever virus have been shown to be present in stomach and tissues of the tick, and the same dies have also been demonstrated in the tissues of fected guinea-pigs.

Another interesting disease of the undetermined oup is sand-fly fever, the virus of which is conveyed om man to man by the sand-fly. A new era in its dy has been opened up by the work of Whittingham d Rook, who have learned how to handle, breed, d keep sand-flies in captivity, and have shown that e virus is transmitted from generation to generation flies without intervening passage through man or her higher animal. The knowledge of the life history the flies will no doubt lead in due course to the ppression of the disease.

Another type of invertebrate vector is the Kedani ite, *Trombicula akamushi*, which transmits the virus Japanese river-fever to man from wild animals. e dangerous character of this disease (Tsutsugamushi) d the minute size of the mite together have pre- nted great difficulties to the Japanese investigators. rotection from the mite by special clothing and thing after exposure to risk of infection are at esent the most hopeful methods of prophylaxis.

Antitoxic sera have also been used with some easure of success in the prevention of diseases of this oup. Degkwitz and others in Germany are reported have been very successful in protecting children om measles and scarlet fever by injecting them with small quantity of serum from convalescent patients. his method has also been found very useful under itable conditions to protect cattle from foot-and- outh disease.

But far more hopeful than protection by serum alone is the use of a vaccine to produce a lasting immunity, combined with antitoxin to prevent the vaccine from producing unpleasant results—the so-called toxin-antitoxin method. Most of the diseases for which this method of prophylaxis has proved valuable have been diseases of animals, such as pleuro-pneumonia of cattle, rinderpest, and foot-and-mouth disease; but quite recently the method of Dick, of Chicago, in scarlet fever has been supported by a number of observations. The system of testing and producing immunity is planned on the same lines as the Schick method for diphtheria.

Dietetic Deficiencies—Deficiency Diseases.

The preceding account is but a short and meagre history of the marvellous advance which has been made in the prevention of infectious diseases in our times, an advance due in great part to the work of two men, Pasteur the Frenchman and Koch the German; those who have come after them have merely followed in their footsteps, been their disciples.

Time will not permit even to touch upon the advances made in the prevention of other important diseases, such as the surgical infections and those caused by intestinal parasites, prominent among which are the hookworms and bilharzia. This advance has not been limited to the infectious group: it has been shared by other groups, notably those due to dietetic deficiencies, the so-called deficiency diseases. These deficiency diseases are just as important, or even more important, than the infectious, since they are always with us and exact an enormous toll in lowered health, lowered vitality, malformation, and inefficiency.

Until a few years ago it was taught in the schools that a complete diet consisted of certain proportions of proteins, carbohydrates, fats, and salts. But our knowledge is constantly increasing, our ideas about things constantly changing, and what is looked on to-day as absolute immutable truth to-morrow is seen in the light of some newer knowledge to be but a crude beginning. So the teaching concerning what constitutes a complete and healthy diet has changed, inasmuch as certain substances have been discovered in food-stuffs in the absence of which an adequate number of calories supplied in the form of proteins, carbohydrates, fats, and salts can alone neither promote growth nor support life indefinitely. These accessory food factors, or vitamins as they have been named, are present in such minute quantities in foods that they have never been isolated, and their chemical composition is therefore unknown. It is still a matter of opinion as to whether they really constitute parts of the structure of living tissues, or whether they merely act as catalysts or stimulators in the process of growth and metabolism. That they are definite chemical

substances which can be added to or removed from a food-stuff, with good or evil results, has, however, been abundantly proved.

The untutored savage living on the natural fruits of the earth and the chase knows no deficiency diseases. It is only when man begins by artificial means to polish his rice, whiten his flour, and tin his beef and vegetables that the trouble begins. Civilised man living in comfort, drawing his food supply from the whole earth and able to vary his dietary at will, is in little danger; but it is otherwise with children and adults living under institutional conditions, with armies on active service, encountering extremes of climate, and with young infants on their naturally restricted diet. While it is true that deficiency diseases will only develop to their well-marked dangerous stage if the deficiency of accessory factor is severe and protracted, a slighter deficiency, if prolonged, may cause a condition of general ill-health and inefficiency not less important although ill defined and difficult to diagnose. This fact is of special importance in the case of infants and young children.

The Discovery of Vitamins.

At the present time, three, and possibly four, distinct vitamins have been described and studied, and it is probably only a matter of time for others to be discovered.

The discovery of vitamins dates to the middle of the eighteenth century. In 1747, James Lind, a surgeon in the British Navy, carried out a series of experimental observations upon sailors suffering from scurvy, the conception and performance of which were entirely admirable. By appropriate control experiments he showed that the medical means in vogue for the treatment of the disease were futile, when not harmful, but that orange and lemon juices were a specific cure. Lind attempted to ascertain the relative anti-scorbutic value of various fruits and green vegetables, but was unable to observe a "superior virtue" in one rather than in another. He confirmed Kramer's observations made at the beginning of the eighteenth century, during the war between the Turks and the Holy Roman Empire, that dried vegetables were useless, and adopts the explanation of his friend Cockburn "that no moisture whatever could restore the natural juices of the plant lost by evaporation," which Cockburn imagined were "altered by a fermentation which they underwent in drying."

Lind was struck with the beneficial effect of cow's milk in the treatment of scurvy. He explained it on the supposition of the milk "being a truly vegetable liquor, an emulsion prepared of the most succulent wholesome herbs." Lind applied himself to the applications of these discoveries for the prevention of scurvy in the Navy, and recommended lemon-juice concentrated to a syrup by evaporation to be carried in all ships and served out to the sailors. By the beginning of th nineteenth century the carriage of lemon-juice was mad compulsory, first in the Navy and subsequently in th mercantile marine, with the result that the ravages o scurvy were prevented. With the advent of steam traction, too, the length of voyages was curtailed an supplies of fresh provisions were obtained at mor frequent intervals. Scurvy became rare, and th medical profession, being no longer faced with th disease of dietary deficiency, soon forgot the significanc of Lind's discoveries.

Before leaving this subject a curious fact may b related. The lemon-juice supplied to the Navy was a first made from lemons grown in Spain and the Mediter ranean countries. Afterwards, when England took ove the West Indies, it was made from the lime, and scurv again broke out. The reason of this is now known t be that, whereas the lemon is particularly rich in anti scorbutic vitamin, the lime is correspondingly poor.

The scientific study of the disease may be said to hav lapsed for a century and a half, until Holst and h co-workers in Copenhagen investigated the etiology o scurvy anew on modern lines, with the help of experi ments on animals. Their work, published in 1907 an 1912, formed the basis for the numerous researche carried out in England and America during and sinc the recent War. As a result of this work the etiolog of scurvy, discovered in effect centuries earlier, has bee firmly established as due to lack of a specific, undeter mined, and as yet unisolated, constituent of fresh foods especially of fresh vegetables and fruits, now known a Vitamin C.

In the meantime the existence of a second vitamin the so-called anti-beri-beri, or anti-neuritic vitamin Vitamin B, had been discovered. Eijkman's admirabl studies at the end of last century, in 1897, on th etiology of beri-beri in the Dutch Indies, brough forward evidence for the view that this disease was o dietetic origin, and was caused by a diet consisting to exclusively of highly milled and polished rice. H showed that the disease could be prevented if the outer layer (or pericarp) and the embryo of the seed, which had been removed in the process of milling, were restored to the "polished" rice. Eijkman's discovery of the analogous disease in birds, *Polyneuritis gallinarum* provided the necessary tool for further investigation o the subject. The researches of Grijns and others showed that the bran and polishings of rice were only one of many rich natural sources of the unknown principle preventing beri-beri, and it became evident that, while the disease is usually confined to tropical races subsisting largely on rice, the European white bread eater is protected only by the varied diet h usually enjoys. Experience on active service show that beri-beri may really develop on a diet of tinned meat and white bread or biscuit.

During the late War two examples of the use made of t s new knowledge occurred in Mesopotamia. At the ginning of the campaign, on account of a difficulty in nsport, there was a shortage of fresh food, with the rious result that scurvy broke out among the Indian ops and beri-beri among the British. The Indians re living on dried pulses, such as peas, beans, and tils; the British on tinned beef and biscuits. The mer diet was deficient in the anti-scorbutic vitamin account of the complete drying of the seeds; the ter in the anti-beri-beri factor on account of the use white flour from which the germ had been removed.

Some years ago it had been discovered that if dried eds are germinated, a quantity of the anti-scorbutic tamin is produced by the act of sprouting. This was ne. The dried peas and beans were soaked in water d then spread out in shallow layers, to cause them to rout, which they readily did in the warm climate. he germinated seeds were then issued to the Indian ops and cooked in the usual way. As a result of this mple procedure the scurvy completely disappeared.

In regard to the British troops it was known that the nti-beri-beri vitamin is contained in large quantities certain cells, and notably in yeast cells. A small antity of this substance in the form of marmite was ded to the soldier's diet of bully-beef and biscuits, d the beri-beri in like manner disappeared.

It may seem strange that the conception of the rôle vitamins in nutrition should have come first from the thologist, and should not have emerged from the portant advances in our knowledge of the physiology nutrition which were made during the second half of he last century. The physiologists were preoccupied ith the chemical composition of food-stuffs and their lue for supplying energy and supporting growth, and ith the necessity for supplying the requisite number of lories in a diet, distributed appropriately among roteins, fats, and carbohydrates, with adequate lection of mineral salts. It was only when these searches led to experiments in which animals were fed pon various mixtures of purified food elements that he investigators in this field began to realise that their peated failures to rear animals upon such carefully rranged diets were not due to accident. The truth as suspected by Lunin in 1881, but it was not until 912 that Hopkins published the classic experiments hich proved the fact beyond a doubt. In the course f work along the same lines in the United States, IcCollum and Davis in 1915 rediscovered Vitamin B, nd, in addition, a third essential dietary constituent, a at-soluble vitamin, present in butter-fat and certain ther fats of animal origin, especially in cod-liver oil nd other fish oils. This vitamin is known as fat-oluble Vitamin A.

Rickets as a Deficiency Disease.

The discovery of the fat-soluble vitamins proved to be of great importance in elucidating the etiology of this disease, which had for long been an unsolved problem. Some authorities had erroneously considered it to be an infectious disease, like tuberculosis. Another school held the so-called Domestication Theory, that it was caused by unnatural surroundings, involving a want of sunlight, fresh air, and exercise. A third considered rickets to be caused by improper feeding, though opinions differed as to the exact nature of the dietetic defect. The conclusion, first put forward by Mellanby in 1918, that a deficiency of fat-soluble vitamins plays a most important part in the causation of the disease is now generally accepted. This has been established by a large amount of work, both experimental and clinical, carried out by Mellanby himself, McCollum and Hess and their respective co-workers in the United States, and Korenchevsky and others in England. It may be laid down that if a young animal is supplied with a sufficiency of these vitamins, rickets will not develop. The question of prevention is therefore one of economics. The difficulty is that these fat-soluble vitamins are chiefly found in such food-stuffs as butter, eggs, the fat of beef and mutton, and fish oils, all expensive articles of diet which the poorer classes can seldom afford. The only "butter" used by them is probably some form of margarine, made from vegetable oils which contain little or no anti-rachitic vitamin. The question of prevention is for the sociologist. Science can only discover the causes and point the means. It is for governments and local authorities to carry out preventive measures in practice, and it is to be feared that science is often far ahead of the community in its share of the work.

Although the theory that rickets is an infectious disease has been exploded, a great and remarkable truth was contained in the domestication and hygienic theories which held that, among other unhygienic conditions, want of sunlight was concerned in the etiology of the disease. During the last five years it has been discovered that exposure to sunlight or to the ultra-violet rays of the mercury vapour quartz lamp can cure rickets in children. Experiments on animals have shown that the effective rays in the sunlight are also the ultra-violet. This discovery has indicated lack of sunlight during winter as one factor concerned in the large spring incidence of the disease in industrial cities in northern climates.

A complete and well-controlled research showing the interaction of diet and light in the prevention and cure of rickets in infants was gained in Vienna, since the War, by Dr. Harriette Chick of the Lister Institute and her four colleagues. There the curious fact came to light that infants fed on a diet deficient in anti-rachitic vitamin developed the disease only in winter and not in summer, and, moreover, could be cured in winter by exposure to artificial forms of radiation or by administration of cod-liver oil without any other change in diet or management. Another set of children who had a sufficient supply of fat-soluble vitamins in their diet, in the form of cod-liver oil, escaped the disease altogether.

Experiments on rats have also shown that in animals fed on a rickets-producing diet, rickets does not occur if the rats are exposed regularly to sunlight or to the rays of the mercury lamp, or other form of artificial ultra-violet radiation; whereas, if they are kept in the dark, rickets does develop. If, on the other hand, the diet is complete in all respects, including abundance of fat-soluble vitamins, the animals do not develop the disease, even if kept constantly in the dark.

How this is brought about is not known. At one time it was thought that the action of the ultra-violet rays on the tissues might enable the animal to syn-

thesise fat-soluble vitamins, as it does in the tissues of plants, but recent evidence brought forward by Miss Margaret Hume in Vienna, and by Goldblatt and Soames at the Lister Institute, suggests that light can neither create nor act as a substitute for the vitamin. It seems rather to act as a stimulant, enabling the animal to make full and economical use of its store of fat-soluble vitamins, and when the store is used up growth ceases in spite of the continued action of the rays.

An important and practical point in regard to the connexion between diet and sunlight and the formation of the anti-rachitic vitamin is the relation to cow's milk. Recent work carried out by Dr. Ethel Luce at the Lister Institute has shown that milk obtained from a cow on pasture in summer contains a sufficiency of the growth-promoting and anti-rachitic fat-soluble vitamins. In winter, on the other hand, if the cow is stall-fed and kept in a dark stable, the milk may become deficient in these respects and young animals fed on it may become rachitic. This work shows that the seasonal variation in quality of the cow's milk may be an additional factor in the seasonal incidence of infants reared upon it. It also disposes of the idea, very current in some quarters, that cow's milk possesses low and negligible anti-rachitic properties and that the anti-rachitic properties of cod-liver oil are specific and peculiar to that substance.

Enough has been said to show that rickets may be regarded as a disease of sunless houses combined with a diet deficient in the anti-rachitic vitamin, and the means of prevention are sufficiently obvious, if not always easy and simple to carry out. Doubtless in the future this new knowledge in regard to the accessory food factors in diet will be used to a greater extent than it has been up to the present, in which case it is not too much to expect that the city children of some future generation will have better-grown bodies and stronger, healthier teeth than their predecessors of the pre-vitamin age. This might be attained in a comparatively near future if only man could be allowed to work out his salvation in peace. Instead of this, great wars come and throw back the work for generations.

To saddle the country with a million and a half of unemployed, with the consequent poverty, insufficient food, clothing and housing, is not calculated to further the prevention of disease and raise the standard of health. Is it too much to hope that in the revolving years a time may come when by a Confederation or League of Nations the world may be so policed that no one country will be able with impunity to attempt the destruction of its neighbour? Until this happens it is difficult to see how rickets, tuberculosis, and other diseases can be adequately dealt with in our city populations.

Diseases due to Ductless Glands

I can only briefly allude to the astonishing advance in our knowledge of the diseases caused by a defect or excess of secretion of the ductless glands. Many of these discoveries are among the fairy tales of science. All this advance has taken place in the comparatively short space of time under review.

Prof. Starling, one of the chief protagonists in this advance, in his Harveian Oration a year ago states this very vividly: "When I compare our present knowledge of the workings of the body, and our powe of interfering with and of controlling those workin for the benefit of humanity, with the ignorance an despairing impotence of my student days, I feel tha I have had the good fortune to see the sun rise on darkened world, and that the life of my contemporarie has coincided not with a renaissance but with a ne birth of man's powers over his environment and h destinies, unparalleled in the whole history of mankin Not but there is still much to be learned: the ocean the unknown still stretches far and wide in front of u but for its exploration we have the light of day to guid us; we know the directions in which we would sai and every day, by the co-operation of all branches science, our means of conveyance are becoming mo swift and sure. Only labour is required to exten almost without limit our understanding of the huma body and our control of its fate."

There is one point of likeness between the vitamin which we have been considering and these glandula secretions, or hormones, as they are named. Just a we have seen that the presence or absence of a extremely minute quantity of a vitamin may determin growth and health or disease and death, so an extremel minute quantity of glandular secretion may have similar effect.

The anterior lobe of the pituitary gland is a ver small body, yet an excess of its secretion will cause child to grow into a giant; a deficiency, and the grow ing child will remain an infant.

The best known of the ductless glands is the thyroid and the effect of its secretion is truly marvellous. deficiency, and the child grows up a heavy-featured gibbering idiot. Rectify the supply of thyroid secre tion; the heavy features disappear, the eyes brighten the intelligence returns, and instead of the forme heavy-jowled imbecile you have a bright, happy, an normal schoolboy. On the other hand, if there is a excess of the thyroid hormone, exophthalmic goitre, o Graves's disease, is the result. Remove the re dundancy and health returns.

The active principle of the thyroid has lately bee shown to be a compound containing iodine. If ther is no iodine in the soil or water, goitre is the result, a in parts of Switzerland, Canada, and the United States This aspect of the subject was taken up some ten year ago by Dr. David Marine and his colleagues at Cleve land, Ohio. They find that endemic goitre may b prevented by the simple method of giving for a tim minute doses of iodine, and conclude that with thi simple, rational, and cheap means of prevention, thi human scourge, which has taken its toll in misery suffering, and death throughout all ages, can and should be controlled, if not eliminated, and look forward i imagination, a few generations hence, to the fina closing of the chapter on endemic goitre and cretinism in every civilised nation in the world.

Many advances have also been made in our know ledge of the function and uses of other ductless glands and, as you know, the latest victory in this field is the discovery of insulin and the successful treatment o severe diabetes, for which magnificent work your own townsmen Banting and Best deserve the highest honour.

In many other directions than those touched upon has there been progress in the prevention of disease

would take more than one address to describe the ivities of the Rockefeller Foundation alone. Cam-gns for the relief and control of hookworm disease, laria control, the eradication of yellow fever, anti-erculosis work and education are being pursued on h a scale and at such a lavish expenditure of money to leave us in the Old Country breathless with miration and envy.

This Foundation, incorporated in 1913, was founded, the words of the president, "to stimulate world-wide earch, to aid the diffusion of knowledge, to encourage operation in medical education and public health." chartered purpose is to promote, not the exclusive sperity of any one nation, but "the well-being of nkind throughout the world."

Science, indeed, knows no boundaries of nations, nguages, or creeds. It is truly international. We all children of one Father. The advance of know-lge in the causation and prevention of disease is not the benefit of any one country, but for all—for the lely African native, deserted by his tribe, dying of eping sickness in the jungle, or the Indian or Chinese coolie dying miserably of beri-beri, just as much as for the citizens of our own towns.

From what has been said, it is abundantly clear that during the comparatively few years that have passed since this Association first met in Canada, enormous advances have been made in the prevention of disease. Before that time we were still in the gloom and shadow of the Dark Ages. Now we have come out into the light. Man has come into his heritage and seems now to possess some particle of the universal creative force in virtue of which he can wrest from Nature the secrets so jealously guarded by her and bend them to his own desire.

But let there be no mistake; much has been done but much more remains to be done. Mankind is still groaning and travailing under a grievous burden and weight of pain, sickness, and disease. Interruptions are sure to come in the future as they have in the past in the work of removing the incubus, but, in spite of these, it is the duty of science to go steadily forward, illuminating the dark places in hope of happier times.

Scientific Problems and Progress.

Abstracts of Addresses of Presidents of Sections of the British Association.

Chemistry and the State.

In Section B (Chemistry) Sir Robert Robertson took "Chemistry and the State" as the subject of his residential address. The relations of the State to hemistry in Britain originated in the necessity for self-rotection; they developed from motives of expediency; nd they have culminated in direct Government aid for search. From the time when gunpowder was first made r the State in the fourteenth century down to the pro-uction of amatol during the late War, the State has ways interested itself in the manufacture of explosives, ut important scientific research in this connexion began nder Abel and his co-workers, Kellner, Deering, ewar, and Dupré, who developed the use of guncotton nd cordite. Outstanding advances in the manufac-ure of explosives emanated from the Royal Gunpowder actory, and general research was carried out both here and in the Research Department, Woolwich. The War caused an enormous expansion of the State's ctivities in the production and investigation of hemical means of defence and offence.

The relations of the State to metallurgy were mostly poradic before 1914, the main advances arising from rivate effort, but Percy, Abel, and Roberts-Austen, ll of whom held official posts, assisted the Government n many inquiries, and more recently notable work on he non-ferrous alloys has been done at the National hysical Laboratory, ferrous metallurgy being studied n the Research Department, Woolwich. The State has always maintained a close connexion with minting, nd many of the Mint officials, including Hofmann, Graham, Miller, Stenhouse, and Roberts-Austen, have made important additions to metallurgical science.

Expediency caused the State to levy duties on lcoholic liquors, tobacco, and other commodities. Richard I. imposed a duty on imported wine, and under Charles II. acts were passed to prevent the mixing and adulteration of wines (it is still illegal to mix wines of different kinds). Accurate methods of testing spirits, etc., have been elaborated in the Government Laboratory, and much work has been done there on the denaturing of alcohol.

Playfair, supported by the Prince Consort, pioneered the direct intervention of the State in sanitation and control of the quality of foodstuffs; investigations on the adulteration of foods and drugs followed and led to the appointment of public analysts, to the extension of the work of the Government Laboratory, to the establishment of the Ministry of Health, and to the formulation of certain definitions and standards for spirits, dairy products, preserving and colouring matters in foods, etc. The State has also promoted or done very valuable work on the purity of water supplies, the disposal of sewage, the contamination of the atmosphere, and has established chemical control of many manufactures dangerous to health.

Although Humphry Davy was a member of the first Board of Agriculture, formed in 1793, progress in agricultural chemistry was left to private enterprise for more than a century; the establishment of the Development Commission in 1909 paved the way to important advances which have originated at Rothamsted and other State-supported institutions. The shortage of fixed nitrogen and of potash during the War made Government action imperative; and the valuable work of the Nitrogen Products Committee has been followed up by the establishment of a nitrogen industry at Billingham-on-Tees, where 150 tons of synthetic ammonia are now being produced daily.

The greatest advances in chemistry have been made in the universities and by private workers, but the contributions from Government institutions have not been unimportant; and the benefit has been mutual. During the War the State recognised its obligation to

foster research, both in pure and applied science. Under the schemes of the Department of Scientific and Industrial Research the smaller chemical manufacturers are co-operating in the investigation of common problems, and the assistance extended by that department to academic workers shows that the State recognises the truth of the dictum that "research in applied science may lead to reforms, but research in pure science leads to revolutions."

Geology in the Service of Man.

Prof. W. W. Watts, president of Section C (Geology), selected "Geology in the Service of Man" as the subject of his presidential address. He pointed out that the mining industry, by providing exposures of rocks in mines, and by demanding as it did accurate knowledge of the nature and structure of the earth's crust, had been an important factor in the growth of the science of geology. He paid a tribute to the early work of Werner and William Smith from this point of view. It is a curious fact that these two pioneers of the science of geology were strongly imbued with a sense of the utility of geological science, and made their contributions to the establishment of the science with an economic motive. During the nineteenth century the purist attitude of mind became dominant among geologists, and it can scarcely be said to have faded out as yet; but, as Prof. Watts remarked, the feeling of mutual suspicion and distrust between the purely scientific and economic workers is fortunately passing away. The scientific and economic workers now find that they are mutually indispensable, and are everywhere co-operating in the work of developing and exploiting the mineral wealth of the earth's crust.

With reference to the study of geology as a factor in educational training, Prof. Watts deplored "the tendency in early education to squeeze out other sciences in favour of those that are called fundamental, and to suppose that, because it makes use of most other sciences, training in geology ought not to be begun until the other sciences have been mastered." He pointed out that, in consequence of this tendency, the habit of close observation is not being cultivated as it should be. The student's early propensity for making observations is blunted unless it be encouraged by studies such as those of practical geology, the pursuit of which has the additional advantage that it gives the student a stronger incentive to the study of the fundamental sciences and shows him their utility.

Under the sub-headings coal, oil, metals etc., stone etc., roads, water, power, agriculture and forestry, military science, geography, and biology, Prof. Watts showed in an interesting way how very wide, permeating, and altogether important are the influences of the science of geology in the service of man. The address will be read with much interest by all who appreciate the economic value of science in general and geology in particular.

Racial Problems and Colonisation.

As president of Section E (Geography), Prof. J. W. Gregory, in his address on "Inter-Racial Problems and White Colonisation in the Tropics," appropriate directed attention to the immense problems of popul tion arising from the unification of the modern world the movements and organisation of commerce. Peopl of very diverse heredity are brought into mass conta and the results are difficult to evaluate, especially prejudices of many and often conflicting types enter in the discussion. Prof. Gregory quotes views on mar points, and scarcely attempts to give an opinion racial fusions; he indicates South America as a regi where such fusion has occurred and is still developi on a large scale, and the United States of America a region where the strongest opposition to such fusion h been offered by both sides. He evidently thinks th the maintenance of black and white side by side b distinct in the U.S.A. is an impossibility, especially view of the increase of southern European elements the population of late years. In that opinion he wi the agreement of a great many thinkers and worker Prof. Gregory, however, scarcely gives attention modern demographic work in the U.S.A., such as th of W. F. Willcox, who claims that in every one of t Northern States negro deaths exceed negro births, an that this is probably true in cities generally. Moreov the negro, as Prof. Gregory shows, is tending to mov to the towns. Willcox and his fellow-workers do n expect the negro to maintain himself at 19 per cen of the population, but argue that in the year 2000 may be only 5 per cent. This, however, may pr suppose a rather large increase of whites, and may n take enough account of the influence of souther Europeans in producing "near whites." At any rat it seems clear that census errors in 1870 have sprea an erroneous idea about increase of negro populatio in U.S.A.

Prof. Gregory touches the South African problen where the "black" is at home and increasing, whi the white finds more difficulty in maintaining himse physically and economically than he seems to indicat He seems right in urging that the Nationalist Labou Coalition in South Africa is based on racial politic with the ideal of black segregation, in the hope th large areas may become homes of pure European The hope is dim enough. Prof. Gregory is enthusiast about the white Australia policy, and upholds strenu ously the view that disease, not climate, is the enem of white settlement in the tropics. From this point view he makes the most of the partial success of Nort Queensland, and discounts failures in the Norther Territory as due largely to lack of organisation, railway etc. At the same time he acknowledges that, whe wet-bulb temperatures are high, the environment against strenuous mental activity, though he does n go so far as does Dr. Leonard Hill towards suggestin that the white man would need to modify himself an his ways in order to occupy Northern Australia seriously Nor does Prof. Gregory mention the probability tha what may drift to Northern Australia may be a Pass-fo White population. He rightly points out that ther are immense spaces that the surplus population China may occupy in Asia, but he does not seriousl refer to the delicate and pressing problem of the crowde population of Japan. It is doubtful whether man Japanese constitutions could stand interior continenta climates in Asia at all. One cannot but welcome a

eresting statement of a position taken up by a much-velled geographer on the most urgent problem of time.

Free Trade Doctrine.

Sir William Ashley took as the subject of his sidential address to Section F (Economic Science d Statistics) "A Retrospect of Free Trade Doctrine." ere is a peculiar appropriateness in both speaker and ject. Sir William Ashley went to Toronto in 1888 occupy the first chair of political economy in Canada; has been throughout his career the chief academic tic of free trade in the English-speaking world. His dress has, however, only an incidental bearing on rrent controversies. The doctrine that he expounds d criticises is the doctrine formulated by Adam ith and his successors, in the century that began th the publication of "The Wealth of Nations" and ded with the new orientation given to economic dies by Jevons and Cliffe Leslie.

Sir William Ashley begins by formulating the ctrine for convenience of reference in nine pro-sitions. Each of these he then expounds with an undance of quotations from representative economists the period, and proceeds to criticise in the light of nomic developments during the period and since its se. In the main the address is an essay in the tory of economic thought, marked by the literary ace and the pleasantly acid wit that characterise r William Ashley's critical work; so far as it has an ject beyond this, it establishes the conclusion that e political doctrine of Smith and Cobden and Mill longs to the thought and conditions of an age that past.

It is the doctrine, not the policy, of free trade with hich the address is concerned, and this the president ows conclusively is based, not on an inductive argu-ent from experience, but on the optimistic philosophy r theology) of Nature that was common to "The heory of Moral Sentiments" and "The Wealth of ations." The identities of phrase in the two are everly used to bring out the a priori character of the tter. Nature is beneficent; it follows that the nrestricted freedom of the individual to pursue his wn interest can have only beneficent effects. Such reedom is a "natural" right; State interference is artificial." It follows that the individual interest nd the social interest are identical, and society is othing more than a collection of individuals. A ubsequent age, with a different philosophy, has had o difficulty in seeing that the use of "Nature" and natural" in these connexions is question-begging. he purely economic elements in the doctrine show ore definitely the influence of contemporary economic onditions; the criticism to which they are subjected s also different. They are tested by reference to conomic facts and conditions of their own and other imes, and their inadequacy brought out. Social olicies have changed as much as social philosophies.

The free trade doctrine was the creation of philo-ophers and the instrument of practical men. This ummary of its content and development brings out he changes that economics had to make in its objects nd methods before it could claim to be scientific. The address is typical of the work which Sir William Ashley has done to free the study from the bonds of mere analytical introspection.

Engineering Position and Prospects.

Prof. G. W. Howe, in his presidential address to the Engineering Section, gave a *résumé* of the advances made in engineering during the last hundred years. He regarded Faraday's discovery of the principle of the electro-motor in 1821 as the birth of electrical engineering. It was not, however, until ten years later that Faraday discovered magneto-electric induction. The early workers did not realise that a dynamo could be used either as a generator of electrical energy or as a motor. Lord Kelvin installed one of the earliest house-lighting installations at 11, The University, Glasgow, in 1881, using a gas engine to drive a Siemens dynamo. The pressure was 85 volts and Swan lamps were used, but Kelvin had to design his own switches and fuses and think out how to support and distribute his lamps.

Prof. Howe mentions that in Glasgow he pays 5*l.* per ton for anthracite to burn in a slow-combustion stove. Assuming that the calorific value of anthracite is 14,000 B.T.U. per lb., this works out at 7·5 kilowatt-hours for a penny. He pays a penny for a kilowatt-hour for heating and cooking. For continuous operation, therefore, the high efficiency and convenience of a slow-combustion stove makes it much the more desirable. When, however, intermittent heating is desired the electric radiator may be the more economical. An interesting account is given of how the output attainable from a given size of machine has been slowly but continuously increased. This is due to the improvements in the electrical, magnetic, and mechanical properties of the materials used as well as to improvements in design. Considering the modern direct current motor, the freedom from trouble of the enormous number of motors in electric trams and trains is a testimony to their trustworthiness.

Prior to 1890 Ferranti had built the Deptford Power Station and was installing large 10,000 volt alternators to supply London with electric light. In 1913 the largest turbo-alternators had an output of 7500 kilowatts. Now, machines of 30,000 kw. and even 60,000 kw. are in operation. Electric traction has absolutely revolutionised the methods of transport within a single generation. Although 500-volt direct current supply has been standardised for tramways, the relative merits of direct current and alternating current for traction purposes are still being discussed. Prof. Howe is inclined to regard three phase supply for traction, notwithstanding its successful application in Northern Italy, as being antiquated. The battle is now confined to direct current at pressures between 1500 and 2000 volts and single phase alternating current. In the latter case the question of the most desirable frequency is not yet settled. The development of the alternating current traction motor during the early years of this century has made possible so many simplifications and economies in transmission that it is yet a moot point whether A.C. or D.C. is best for main line electrification.

Within the last thirty years the provision of an

abundant supply of electric power has led to the creation of enormous electro-chemical industries. The production of aluminium, carborundum and calcium carbide by electrical energy obtained from waterfalls may be specially mentioned. In 1926 the jubilee of the invention of the telephone by Alexander Graham Bell will be celebrated. The great advances recently made in automatic telephone stations where the operator is entirely eliminated and the subscriber himself makes the required connexion are well described as marvellous. What were considered wild dreams, twenty years ago, of the future of radio-communication have been completely realised in everyday practice. The commonplace radio-broadcasting of to-day appeared outside the bounds of possibility a few years ago. Thirty years ago a ship at sea was completely isolated from the life and thought of the world. It is now in continuous communication with the land and with every ship within a range of many miles. Prof. Howe points out that in no branch of electrical engineering is there any question of finality being attained. Rapid development is taking place in every direction, and new natural sources of energy are continually being utilised for the benefit of humanity.

National Health and Physique.

In his presidential address to the Section of Anthropology, on "Health and Physique through the Centuries," Dr. F. C. Shrubsall reviews some of the evidence relating to improvement or deterioration in national physique from early times, and more especially under industrial conditions. Referring to the recent recruiting experience in Britain, he rightly points out that the National Service Survey of 1917–18 covered a population from which the best physical material had already been taken, and the marked inferiority in the average stature deduced from these returns as compared with that of recruits of British parentage drafted from the United States may be partly due to this fact, but also no doubt to the tendency of the best physical types to emigrate. School medical and recruiting data agree in showing the inferiority of the industrial as compared with the rural populations both in stature and general physique, but we are told that there is little or no evidence of deterioration of any one racial type in either respect since the beginning of the industrial era, but rather the reverse. The great increase in the expectation of life at the younger ages, which has undoubtedly occurred since Roman times, has been accelerated in the last two decades, as shown by the most recent life tables. The falling death-rate and improved health of the towns must be largely due to gradual removal of adverse conditions of labour, housing, and sanitation, which probably reached their worst level early in the last century, with the consequent stamping out of certain epidemic diseases and reduction in infant and adult mortality.

To proceed from this, however, to draw the conclusion that we are therefore physically and mentally a fitter race is only, it may be urged, to create a false sense of security. The evidence that there has been an advance in physical and mental characters at all comparable with the improvement in environment, if at all, is most inconclusive, though it cannot be doubted that such changes are making the race happier. The ten ency of public health measures to aid the survival inferior stocks may on the contrary have the rever effect, and the declining fertility and marriage rate the classes with the best physique in recent years is matter of serious import for the future. Such euger considerations, which are of primary importance in t determination of national physique, are scarcely giv their full weight in the address, and its optimistic to will not appear to all students of racial problems be justified by the facts.

The closing plea for an extension of anthropometr investigations in Britain, using the term in its wid sense, is, however, well worthy of consideration, for, quote from the address, "it is only on the basis careful physical and mental surveys that legislati directed towards social and racial hygiene cou properly be introduced and rightly justified." Wh the Board of Education refuses to countenance t loss of half a day's education for the purpose of anthropometric research on modern lines on t adolescent boys of a London school, one can on conclude that Britain has not yet awakened to the fa that the lack of such information in this country is deplorable handicap to the intelligent discussion such questions.

Specific Treatment of Infections by Artificia Remedies.

For his presidential address before Section (Physiology), Dr. H. H. Dale chose for his subje "Progress and Prospects in Chemotherapy," which l defined as the specific treatment of infections b artificial remedies. He showed how recent investig tions have attempted to solve the difficult problem the method of action of specific remedies. The vie that a drug acts as a direct poison to the parasite is qui insufficient, as also is Ehrlich's doctrine that in order be specific a drug must have a maximal affinity for t parasite and a minimal one for the tissues of the hos It is becoming increasingly evident that drugs a favourably not only as a result of any action they ma have on the parasite, but by virtue of the response the tissues of the host. Ehrlich and Shiga showed tha Trypan red would cure a mouse infected with *Trypan soma equinum*, but that it failed in the case of t guinea-pig, rat and dog infected with the same trypan some. Similarly Bayer "205" rids mice of trypan some infections but is much less active in the san trypanosomes in the ox and horse.

It is evident that the host factor plays an importar part in the curative process. Ehrlich found during h experiments with atoxyl that strains of trypanosom became resistant to the drug, and that this was mair tained though the virus was passed through a long seri of mice. Mesnil and Brimont, however, showed tha if the virus was passed into the rat it was no longe resistant, though when again inoculated into mice th resistance became at once apparent. It would seer that the trypanosomes in the mice had become toleran not of atoxyl itself but of some product resulting fro the action of atoxyl on the tissues of the mouse, thoug still remaining susceptible to a similar substance de rived from the action of the drug on the tissues of the ra

Neither Trypan blue nor Bayer "205"—and this is e of many other specific remedies—has any visible icity for trypanosomes when applied to them *in o*, though some physiological change is brought about demonstrated by a loss of virulence. Salvarsan has lethal action on spirochætes or trypanosomes *in o*, but after reduction to the corresponding arsenoxide is intensely toxic to them. Voegtlin and his co-rkers have produced evidence that such a reduction oxidation resulting from contact of the drug with the sues of the host accounts for its remarkable action in rochæte and trypanosome infections. Levaditi monstrated that atoxyl became lethal to trypano-nes *in vitro* after it had been incubated with an ulsion of liver, and he supposed that the actual ative agent was a substance "trypanotoxyl" result-from a combination of atoxyl with some constituent the liver or other tissue. Similarly, the therapeutic ion of bismuth salts was attributed by Levaditi and olau to a similarly produced "bismoxyl." Voegtlin s shown that the toxic action of the organic arsen-ides on trypanosomes and host tissues is depressed various sulphydrile compounds are injected simul-neously with the drug, and as a result of the work of pkins he has suggested that the resistant strains erred to above may be due to the trypanosomes ving acquired a capacity for producing such sulphy-dle compounds in excess of their vital needs.

Another illustration of the participation of the sues of the host is seen in the case of emetin in amœbic sentery. The alkaloid has no action on the amœbæ *vitro*, but is endowed with remarkable therapeutic perties when administered to human beings suffer-ig from this infection. It appears to have little or action on the same infection in cats. Whether the ug so affects the human tissues that they are no longer pable of affording nourishment to the amœbæ, or ether the amœbæ themselves are weakened so that ey fall victims to the natural protective power of the st are problems which still await solution. Morgen-th has expressed the opinion that quinine acts in alaria by combining with the red blood corpuscles d so rendering them unsuitable for invasion by the ung parasites.

The tissues of the host may influence the action of a ug in another way. They may fix the drug so that rapid excretion is prevented and by a gradual libera-n of small quantities of the drug itself, or of some bstance they have elaborated from it, prolong the tion on the parasite. Morgenroth has shown that 'Rivanol" is fixed by the red blood corpuscles or bcutaneous tissues and in inflammatory conditions e to streptococci it is gradually given up and retards e development of the cocci. Similarly Bayer "205" held up in the body for long periods, for animals nich have received a dose of the drug are protected ainst infection, while the serum of such an animal may tually bring about a cure in one already infected. has been shown that Bayer "205" enters into com-nation with certain constituents of the blood which thereby altered in character.

It is along lines such as these that chemotherapeutic vestigations are being conducted, and though in any cases it has appeared that specific remedies have en discovered empirically, during recent years advances have been made which go far towards affording a rational explanation of the various mechanisms involved in their action and which, in the future, will yield results of importance from the point of view of practical therapeutics.

Purposive Striving as a Fundamental Category of Psychology.

Psychology is something of a newcomer among the sciences, so that it is not surprising that there should be doubt about its standing among its older sisters. Psychologists are not quite sure what it is that they are studying, or how they should study it. Some of them doubt whether their subject is a branch of physical science at all; others think it would be valueless if it were not. Prof. W. McDougall devotes his presidential address to the Psychological Section to reassuring his faint-hearted colleagues. He insists that it is the business of the psychologist to study his subject by any and every means within his power, without casting side glances at what the students of physical sciences are doing or troubling about what they may be thinking about him. Above all, he should not restrict the scope of his inquiries for the sake of preconceptions about what is correct scientific procedure; the end will justify the means. He rebukes equally the "behaviourists," who want to confine themselves to purely physical methods, and the subjective school, who refuse to make use of observation of physical processes. He rebukes also those who try to belong to both schools with the help of the doctrine of psycho-physical parallelism.

Prof. McDougall conceives of psychology as the study of human nature, and therefore psychologists must take account of all the facts of human nature whether they like them or not. No intelligent discussion of human affairs is possible, as he points out, without the use of such terms as motive, intention, desire, will, responsibility, aspiration, ideal, striving, effort, interest, all of which involve the notion of purposiveness. Any system of psychology which excludes such a notion or explains it away is doomed to sterility and can never find much application to practical affairs. Applied psychology is now a reality both in medicine and industry. Those who have been successful in this field have not been doctrinaire "behaviourists" or subjectivists, but observers who have been ready to study the facts in any way they could and leave the theories to look after themselves. This is very sound advice of Prof. McDougall's, and might well be taken to heart by students of all possible branches of knowledge.

Physiological Aspects of Parasitism.

In his address to Section K (Botany), the president, Prof. V. H. Blackman, dealt with the relationship of host and parasite and their mutual reactions. The differences between animal and plant pathology were first noticed, notably that relating to disease-resistance. In animals, the resistance mostly studied has been acquired immunity, a type not known in the plant world, where the resistance existing is natural immunity. Whatever be the behaviour of individual

cells in plants after a parasitic attack, there is no acquired resistance and no general bodily reaction to disease, hence the application of serum therapy would appear to be precluded. Even if such sera could be prepared, there would be the difficulty of transmitting the substances throughout the plant-tissues and the passing on of the immunity acquired to the new organs which are constantly developing.

With regard to the processes concerned with the achievement of parasitism in plants, the two chief modes of entry, apart from wounds, are through stomatal pores or by actual penetration. The entry through the stoma is clearly the most facile one (though the nature of the reaction which brings it about is still obscure), and it is somewhat of a biological puzzle that any germ-tube should follow the hard road of epidermal penetration. The probability of a negative chemotropism of the germ-tube to its own waste products playing any considerable part in the process does not appear to be very strong, and the evidence for a positive chemotropism to substances diffusing from the host cells is insufficient. It would seem, therefore, that a contact stimulus must play the major part, though it is unlikely that thigmotropism (stereotropism is suggested as a more satisfactory term) is alone responsible for penetration. With regard to the actual mechanism involved, Prof. Blackman and his colleagues have put forward strong evidence for the view that the process is purely mechanical and that enzymes play no part.

The elucidation of the quality of natural infection has been studied particularly in the Erysiphaceæ and Uredineæ. In the latter group, Biffen and his colleagues have shown that resistance in *Puccinia glumarum* in wheat is really the result of hypersensitiveness. The mesophyll cells of the resistant variety are readily infected, but the infected cells react so violently that they are killed and the invading parasitic hyphæ with them. Hypersensitiveness has been shown by Stakman to be the key to resistance of American wheats to *P. graminis f. tritici*. There is no recovery of attacked cells and no production of antibodies either in susceptible or resistant forms. The difference in the behaviour between the cells of the two classes must lie in the differences in the normal physiological processes. Hence this aspect of plant pathology is dependent for its advance on plant physiology.

Academic Freedom.

Principal Ernest Barker's presidential address to Section L (Educational Science), on "The Nature and Conditions of Academic Freedom in Universities," is opportune and much to the point. For one thing, the remarkable growth of modern universities in England in the last two decades has raised the question of academic freedom in a new form, and for another, a little clear thinking upon a subject with so many ramifications is very desirable. Dr. Barker realises the "tangled web of environment" in which the modern university is placed, and does something to unravel it. His analysis is clear, logical, and thorough. At the outset he makes a very proper distinction between the freedom of the teacher and that of the university. He then proceeds to discuss each separately and in some detail.

Perhaps the first part of Dr. Barker's discussion will prove more interesting to the average university teacher than the second. In it he deals with the freedom of the teacher, and, true to his own principles, does not hesitate to express himself with that frankness and freedom which he desiderates. He raises many points and has something of interest to say on most of them. While we may agree with him that a "professor is wise to be severely moderate and master of himself," he will probably agree with us that such wisdom, without occasional relapses, would make academic life, to say the least, somewhat dull. Again, while we may agree with him that "it is difficult to be at once a publicist and a scholar," he will probably agree with us that if professors had become publicists only "in the gravest emergency," public life would have been much the poorer for the limitation. His remarks upon the difficulties which may arise in handling such subjects as history, government, economics, and modern languages are specially pertinent, and it may well be true, as he seems to think, that the cause of academic freedom in the future will be fought with regard to chairs connected with the subjects of politics and economics.

It would have been interesting to have had Dr. Barker's views on university teachers as parliamentary candidates. He seems to think that such candidatures raise "desperate difficulties," but does not state what these difficulties are. Perhaps they are not so great as he thinks, and it may be that there would be advantages largely outweighing them. Here it would seem that Dr. Barker, contrary to his usual practice, passes over an important issue, and one which will become increasingly important in the future. Again, it is curious and apparently illogical for so doughty a champion of academic freedom to suggest that the professoriate should elaborate and *enforce* among themselves a code of professional conduct. It would be immensely interesting to attend a conference or council which set out to draw up such a code! With two qualifications Dr. Barker, so far as the individual professor is concerned, is in favour as a general principle of freedom uncontrolled by any assumption of responsibility by the university.

With regard to the second part of the address dealing with the broader question of the freedom of the whole academic community, Dr. Barker, after a short historical reference, confines himself largely to the discussion of university finance and its general effect upon academic freedom. Here, again, the whole position is thoroughly probed and its many implications carefully considered. The whole address is thought-provoking, exceedingly well handled, and a distinct contribution to a subject of vital importance.

Crystals and Cells.

UNTIL very recent years, the addresses of presidents of Sections of the British Association were never made subjects of formal discussion. The address delivered on Monday, August 11, by Sir William Bragg to Section A (Mathematical and Physical Science) of the British Association meeting at Toronto departed from the former custom in being an introduction to a joint discussion with Section B (Chemistry), on crystal structure. Sir William Bragg explained how X-rays have made it possible to analyse the structure of crystals, thus opening up the chemistry of the solid. The X-rays tell us the number of molecules in the crystal unit and the mode of their arrangement, on which, of course, many properties of the substance depend. It may be noted that just as there are *atoms* of silicon and of oxygen, and a *molecule* of silicon dioxide, so there is a *crystal unit* of quartz consisting of three molecules of silicon dioxide arranged in a particular way. There are thirty-two classes of crystals, according to the kind of external symmetry which they display; but now that he can look into the interior of the crystal, Sir William Bragg finds that there are 230 different modes of internal arrangement. This is a new kind of crystal-gazing.

It has often been asked why a crystal should grow ("Lapides crescunt," said Linnæus) in a solution, especially when the substance in solution is different from that of the crystal, though crystallising in the same style of architecture. There is a welcome beam of light in Prof. Desch's paper on the crystal surface, for it shows that the aplomb of the atoms on the space lattice of the interior, where they are held in position by forces symmetrically disposed, is not shared by those on the surface layer, where there is surface tension and a welcoming, so to speak, of support by accretion from without. At high temperatures, it is noted, the surface tension may be sufficient to cause rounding of the sharp angles of a crystal.

The key-note of the Toronto meeting seems to be "control," for we find Prof. F. W. Gamble, in his presidential address, telling the zoologists that "zoological problems have become problems of control," not so much in the way of restraint as of "quickening." "The infinitely varied animal fabric appears to be the exquisitely balanced individual expression of processes that quicken and restrain." "If to succeed is to come up from below, the actual animal life that succeeds must be but a fraction of the submerged recessive life that experiment reveals. These recessives when artificially bred are no mere cripples, nor disconnected with the evolution of normals. They show us something of the depths of animal nature, and help us to realise that

but for the grace of organic regulation we should be even as they. But the study of such analysis as a branch of zoology leads to an even more striking result. Not only does it reveal the existence of these sub-normals, but also it accounts for the defection of certain expected offspring. There are non-viable combinations of living substances. These entering the egg that should by expectation produce a male, render the egg incapable of development. That family will be one of daughters only. The existence and the control of lethal factors is one of the most significant discoveries of the underworld."

Prof. Gamble is a strong swimmer and he led his audience into deep waters in his discussion of Prof. Child's hypothesis of metabolic gradients. That is to say, there is in an animal like a Planarian worm a gradation in the intensity of chemical change or metabolism from the head backwards. The rate increases again at a point far down the body and then falls to the tail-end. The second, smaller peak marks the place where the worm divides transversely in its asexual multiplication; it marks the site of the future head of the coming daughter! Prof. Gamble regards the suggestiveness of the evidence in support of the gradient hypothesis as exceeding its conclusiveness for the time being. He goes on to discuss with insight the periodicity of vital functions, the problem of nervous control, the control of environment, and the lightening of the eyes that will come when people take zoology seriously.

In his address to Section M (Agriculture), Sir John Russell discussed "Present-day Problems in Crop Production." One of the big conclusions that has emerged of recent years is that the plant is an even more plastic organisation than we thought; it can be moulded to a notable extent, though within certain—very uncertain—limits. One way of doing this is the Mendelian method of picking out desirable unit characters from plants in which they occur and assembling them in a new plant. The other way is selection, in which a desirable plant is caused to produce seed from which stocks are multiplied. A second generalisation is that the soil is not a fixed, constant thing, but is pulsating with change. The micro-organisms fluctuate continually, and even the mineral part of the soil is not constant in composition. "Modern research work shows that many of the properties determining fertility in soils are due to the soil colloids, and some of the most important are attributable to calcium complexes. These are unstable and are affected by the soil water."

Sir John Russell spoke of the control of the plant, the control of environmental factors (for example, by high-tension electric discharge), the control of soil factors, and the control of soil organisms. But he sounded another note, too seldom heard in the utilitarian days; he spoke eloquently of the value science for its own sake. "How many farmers kno anything about the remarkable structure of the so they till, of its fascinating history, of the teemin population of living organisms that dwell in its da recesses, of the wonderful wheel of life. . . ." "N one knows much of these things; but if we knew mor and could tell it as it deserves to be told, we shou have a story that would make the wildest romance human imagination seem tame by comparison, an would dispel for ever the illusion that the country a dull place to live in." This is well said. Trust th agriculturist, fundamental utilitarian as he is, to b loyal to the life that is more than meat.

A familiar experience at meetings of the Briti Association, especially if one wanders out of "one own Section," is a coercive abandonment of facts an conclusions which one had treasured as absolute certain. This holds for the Toronto meeting. Th it used to be common teaching that the earliest Pr Cambrian rocks represented the original crust of th earth, formed as it cooled from a molten to a sol condition. This was a comfortable view, for it ga one, so to speak, a geological jumping-off place. B Prof. A. P. Coleman has punctured our illusions in h paper on "Pre-Cambrian Climates." For it seem that there was before the Cambrian a long period desert conditions and a making of red sandstones before that was a time of cool moist climate and making of grey carbonaceous slates; and before th there was a Huronian Ice Age. "Below this, after profound break, is the Sudbury or Timiskaming serie mostly of water-deposited materials, including 40 feet of well-banded greywacke and slate, evidently seasonal origin. This gritty but well-establishe material and some boulder conglomerates make o suspect a cold and perhaps glacial climate." So th story runs; and the Pre-Cambrian basis, once regarde as primordial, is shown to have behind it a stupendo history.

It is well known that two forms of digestion—intr cellular and extra-cellular—occur among animal Intra-cellular digestion, where the food is taken in ingestive cells and then digested, occurs, as Mr. F. Potts points out, in sponges, stinging animals, fl worms, and molluscs, often accompanied, however, b the extra-cellular method where the secretion of digestive juice dissolves the food in the cavity of th food-canal. The latter is the exclusive method Annelids, Arthropods, Echinoderms, and some small phyla. "In the Gastropod Molluscs digestion in th flesh-eating forms is mainly extra-cellular; in th

vegetarians it is largely intra-cellular." In some cases of specialised diet the intra-cellular method is prominent, as Mr. Potts illustrates by the case of the wood-boring Teredo. In some wood-eating Arthropods like termites, in which there is no intra-cellular digestion, the function has been taken over by symbiotic Infusorians.

In an interesting study of sex-development in fowls, Dr. F. A. E. Crew propounds the view that the genetic constitution of the individual determines what may be called the internal environment in the direction of "femaleness" or of "maleness." "In an internal environment of 'femaleness' the embryonic gonad becomes an ovary, in one of 'maleness' a testis. The bird has an ovary because she is a female, a testis because he is a male. The type of plumage is determined by the type of metabolism which obtains at the time of its development, and is not a response to any specific influence of an internal secretion elaborated by the differentiated gonad." The physiological theory of sex, championed by Geddes and Thomson long ago, is having its innings.

Dr. F. A. Dixey's paper on the minute scent-distributing structures in white butterflies is of noteworthy interest. There are secretory cells and distributing scales. The scent-distributing scale is usually a rather highly specialised structure, often in the form of a flattened lamina provided distally with a fringe of chitinous filaments, and proximally with a fine flexible footstalk. The latter expands into an accessory disc, very varied in size and character. The disc is inserted into a specialised socket, within or beneath which are found the cells that secrete the scent. Everything is so minute that it is difficult to be sure how the scent escapes. Dr. Dixey finds no convincing evidence of pores, and inclines to Weismann's view, that the scented material passes from the secretory cells into the disc, the footstalk, and the lamina.

The physiologists continue to discover new rôles for hormones. Thus Prof. W. B. Cannon and Dr. A. Querido find that adrenal secretion is increased in animals when there is liability to lowered temperature by heat loss. The increased secretion brings about an increased metabolism, a chemical calorigenesis, quite apart from the muscular movements of shivering. So the animal has two distinct lines of defence. In another paper by Prof. A. T. Cameron, Dr. T. Ingvaldsen, and Dr. J. Carmichael, evidence is brought forward to support the view that the internal secretion of the thyroid is a compound of thyroxin with some other radical which considerably increases its activity.

Prof. H. Wasteneys and Mr. H. Borsook have succeeded in effecting the enzymatic synthesis of protein in peptic digests of albumin. The maximum synthesis so far obtained has been 39 per cent. There is "incontrovertible evidence" that the material synthesised is of the order of complexity of native proteins. The enzyme responsible for the synthesis was found to be inseparable in every respect from the enzyme effecting the hydrolysis of proteins.

Every one is familiar with the feeling of having seen the same thing before, though one knows that it could not be so. This is the phenomenon of "déjà vu," which Grasset and Freud have explained as due to the activation of an unconscious memory of a real event, a fantasy, or a dream, which in some way resembles the coincident, conscious perception. The problem has been rediscussed by Dr. J. T. MacCurdy, who has found a somewhat analogous pathological phenomenon —the perplexity case—apparently with a similar obsessive suggestion of familiarity. As often happens, the pathological throws light on the normal.

Prof. G. H. Parker has been able to determine the amounts of carbon dioxide excreted by the lateral line nerve of the dog-fish, the sciatic nerve of the frog, and the ventral nerve cord of the lobster. The quiescent frog nerve produced on the average nine-thousandths of a milligram of carbon dioxide per gram of nerve per minute. In active nerve this was increased by about twelve per cent. Weight for weight, the resting frog nerve produces about the same amount of carbon dioxide as the resting human body does.

These, however, are scarcely more than random comments upon a few of the extraordinarily interesting series of addresses and papers presented at Toronto. A more adequate survey of the wide range of subjects brought before the various Sections must be reserved for later issues.

The Metallurgy of Iron and Steel.

(1) *Lehrbuch der Eisenhüttenkunde: verfasst für den Unterricht, den Betrieb und das Entwerfen von Eisenhüttenanlagen.* Von Prof. Dr. Bernhard Osann. Zweite neubearbeitete und erweiterte Auflage. Erster Band: Roheisenerzeugung. Pp. xi+923. (Leipzig: Wilhelm Engelmann, 1923.) 29*s*.

(2) *The Metallurgy of Steel.* By F. W. Harbord and J. W. Hall. (Griffin's Metallurgical Series.) Seventh edition, thoroughly revised. Vol. 1: Metallurgy; by F. W. Harbord. Pp. xii+545+41 plates. Vol. 2: Mechanical Treatment; by J. W. Hall. Pp. xv+553+42 plates. (London: C. Griffin and Co., Ltd., 1923.) 32*s*. net each vol.

WHILST primitive methods of making malleable iron or steel were mainly conducted in such a way that the product was obtained directly from the

ore without a preliminary fusion, almost the whole of the modern product is obtained in the first instance as pig-iron, a readily fusible mixture of iron with carbon, silicon, and other elements derived from the ore and the fuel, these impurities being afterwards removed by processes based on differential oxidation. This round-about method has proved in practice to have such great advantages, both chemical and economic, that it has become the universal practice. Attempts now being made to re-introduce the old direct process in a greatly improved form have to contend against the fact that smelting in the blast-furnace, at first sight a crude device for extracting iron from its ores, has reached a condition of high efficiency, making it very difficult for a new process to prove any superiority in economy, whatever its apparent theoretical advantages.

In spite of the fundamental importance of the blast-furnace, it has received less attention from scientific metallurgists than the processes for converting its product, the crude pig-iron, into steel. It is true that the pioneer work of Playfair and Lowthian Bell, which gave a scientific basis to the chemical process of ore reduction, has been followed by many interesting researches on the equilibrium between iron, its oxides and the oxides of carbon, but even these reactions are not yet perfectly understood, and most improvements in the operations have been made empirically. Such scientific work as has been done is mostly German, and Prof. Osann's book (1) is greatly superior to works which are little more than catalogues of plant.

The new edition of this treatise, which is the first volume of a comprehensive work on the metallurgy of iron, is of very great interest. Its attractive form and its 550 admirably clear illustrations will make it popular, and it contains information of a detailed kind on the construction and working of the blast-furnace and on such closely connected subjects as the preparation of coke and the utilisation of blast-furnace gas. Certain limitations should be recognised. German, and to some extent American, practice is described, but references to the practice in other countries is only occasional, and not always accurate; the map of the British coalfields on p. 115, for example, failing to show coal in either Yorkshire or Lancashire, and being erroneous in several other respects.

With very few exceptions, all references to literature are taken from *Stahl und Eisen*, so that the remarkable work of the Geophysical Laboratory of Washington on the constituents of slags, the equilibrium diagrams of which are reproduced, is attributed to the writer who abstracted the publications for that journal. The interesting survey of the economic conditions c iron production in the principal countries of the worl is dated 1913, the author stating that the presen conditions are so chaotic as to make a systemati review impossible.

In addition to its character of an encyclopædia of th construction and use of the blast-furnace, the work i remarkable for the amount of space given to calcula tions. An effort has been made to give a quantitativ treatment of every aspect of the industry, and this par of the work is to be highly commended. The studen will find it a profitable exercise to work carefully throug a number of the calculations given by Prof. Osann, an in so doing will be impressed by the necessity for main taining exactly the balance between a number of factors on which the efficiency of the furnace depends. Th English reader will do well to compare the importan paper by F. Clements in the Journal of the Iron and Stee Institute for 1920, in which he will find the quantitativ data for English blast-furnaces, worked out in deta with all the necessary information for determining th efficiency. With such material before the student there is no longer any excuse for the academic neglec of the subject of the smelting of pig-iron which has s long prevailed.

There are some defects in the arrangement of th book, a subject being sometimes cut up into separat sections, which are scattered through different chapter without apparent reason. The full table of content and good index make this defect less serious, althoug irritating. Casting in the pig-bed only receives a fe lines, although machine casting in moulds is rather mor fully described, and it is not clear why so essential part of the process should be neglected. The physica chemistry of the work is rather weak, and occasionall some bad mistakes are made, as in the account o "mixed crystals" on p. 622, but a real attempt ha been made to give an account of the chemistry of iro smelting, and the survey of the chemistry of slags i more satisfactory. Revision of the purely scientifi sections by a physical chemist would be of advantage but with this reservation the book may be recommende to metallurgists generally.

(2) The seventh edition of this, the most importan English text-book on the manufacture of steel, is greatl enlarged, and now forms two massive volumes, whic are sold separately. Since its last revision, progress i the design of plant, in methods of working, and abov all in the scientific understanding of technical processes has made changes in the presentation of the subject t students very necessary. To revise a work of such wid scope, full of illustrations and tables, is naturally difficult matter, and it is perhaps not surprising to find

hat the revision of the first volume, especially, leaves nuch to be desired.

To give a clear and systematic account of the industry s it exists to-day would have meant the complete re-riting of much of the book, and the easier plan, of nterpolating new material at intervals and revising ortions only, has been adopted. The consequence is hat whilst the new edition of Harbord and Hall must etain its place as the standard work of reference on he metallurgy of steel, the serious student or practical teel-maker will often turn to it in vain for information s to the practice or knowledge of the present day, and t other times will find descriptions of processes or tatements of theory which are antiquated, using he word in the relative sense which is natural in onnexion with a subject which makes such rapid dvances.

The defect is most noticeable on the scientific side. he accounts of the physical chemistry of the iron-arbon system, and of the influence of temperature nd other conditions, including the presence of foreign lements, show the grafting of fragments of new know-dge on to the old stock, whilst the student of to-day eeds a clear summary of the state of existing know-dge, incorporating the discoveries which have been eached by modern methods. In a work which is less istorical than practical, it is disappointing to find so uch space given up to dead controversies, the interest which has disappeared owing to the introduction of ew methods. For example, the rival views as to the ature of β-iron and its part in the hardening process ave ceased to be of interest since magnetic observa-ons and, above all, the method of X-ray analysis have moved all doubt on the subject. For the same reason n account of the modern method of preparing micro-ctions would have been preferable to the long record f methods employed by successive investigators with ss perfect technique. Moreover, the scientific study f the relations between the components of molten pig-on and the oxidising agents which bring about its nversion into steel has made immense progress, which ceives no attention in the work before us, the old ermochemical equations which served as a rough uide representing only a part of the story. A good rvey of this important field is still lacking, although nglish chemists have contributed much by their vestigations.

Closely connected with this subject is the question f the distribution and influence of segregated im-urities and of non-metallic inclusions, the importance f which in determining the quality of steel is now fully cknowledged. The evils due to these causes may be rgely eliminated by the choice of suitable methods of casting; but on this matter scarcely any information is given, and the student will have to refer to other works. Another section calling for drastic revision is that dealing with alloy steels. This branch of the industry has developed so rapidly as to make the information given in earlier editions obsolete, and it would have been better to omit the accounts of early work, except so far as is necessary to present the historical aspect of discovery, and to replace them by a modern statement of the alloy steels actually found in use, with a scientific account of their heat treatment and of its relation to constitution. The fact is that the steel industry has passed beyond the stage of empirical control, and has become scientific, and no text-book can be regarded as quite satisfactory which does not indicate the connexion between science and practice. It is to be hoped that a bold effort will be made in the preparation of the next edition to remove obsolete matter, and to replace it by descriptions more nearly representing the actual state of metallurgical science.

The second volume, dealing with the mechanical treatment of steel, is not open to quite the same objections. Such treatment is still mainly empirical, and the scientific calculation of stresses in rolling and forging has only been undertaken by a few persons, whose work is not very generally known. The account of modern plant is adequate, and constitutes a valuable collection of practical information. The chapter on wire, especially wire for ropes, fails to represent modern practice, but in the main new processes are well described. The position of this well-known text-book in metallurgical literature is a deservedly high one, and it has been thought well to direct attention to its shortcomings, in the hope that they will be remedied.

High Frequency Spectra.

Spektroscopie der Röntgenstrahlen. Von Prof. Dr. Manne Siegbahn. Pp. vi+257. (Berlin: Julius Springer, 1924.) 3.60 dollars.

OF the many fields of physics which have been extensively explored during the past decade, none, perhaps, has yielded a greater contribution to our knowledge of atomic structure than that of X-ray spectroscopy. Since the classical experiments of Moseley in 1913–14, the development of the subject has been rapid, and we have now at our disposal a very extensive knowledge of the X-ray emission and absorption spectra of the elements. The time was therefore ripe for the publication of a volume devoted, almost entirely, to a discussion of the methods and results of

X-ray spectroscopy. The present monograph is all the more welcome as coming from the pen of Prof. Siegbahn, who has contributed more than any other to the development of the technique of accurate wave-length measurements in this region of the spectrum.

Prof. Siegbahn's attitude towards his subject is essentially that of the experimental physicist. His main object is to give a full account of the experimental data at present available, and from these to deduce the laws governing the emission of X-ray spectra. Theoretical considerations are introduced in the interpretation of these laws, but throughout the volume the experimental side is emphasised and theory allocated to a secondary position. In such a volume it is natural to find a very considerable section devoted to detailed descriptions of the various methods used in the experimental work. These descriptions, accompanied as they are by excellent drawings and plates, will prove invaluable not only to those who are interested in the determination of X-ray wave-lengths, but also to all who wish to be acquainted with modern X-ray technique. The author is an acknowledged authority on this subject, and anything he has to say in this connexion is well worthy of consideration.

The discussion of the K,L,M, etc. series follows more or less conventional lines. Very complete tables of the latest accurate measurements are given, both for the emission and for the absorption spectra. At present the accuracy of the determination of X-ray wave-lengths must depend on that of other physical constants, but it is no small achievement that, after so short a time, it should be possible in many cases to determine relative wave-lengths to six significant figures. The author emphasises certain experimental work which has so far not received attention in other books on the subject. Most noticeable, perhaps, in this connexion, is the account of the remarkable experiments of Lindh and others on the dependence of the absorption bands of such elements as chlorine and sulphur on their state of chemical combination. This is the first definitely established case of the influence of molecular combination on these phenomena. Now that it has been shown that the valency of the atom in the molecule affects the position of the edge of its absorption band, physicists and chemists alike will await with interest further work in this direction. The whole treatment of the absorption and emission spectra is excellent. Not only are tables of wave-lengths given but also of frequencies (ν/R and $\sqrt{\nu/R}$); a few obvious inaccuracies have crept into these tables, but they are not such as are likely to lead to any confusion.

An admirable section is devoted to the more theoretical side of the problem. Mathematical treatment h been avoided, but the description of the principles la down by Bohr and Sommerfeld is sufficient to enal the reader to follow with interest the extraordinari successful manner in which theory has kept pace wi experimental progress. The existence of doublets constant frequency difference, the connexion betwe one series and another, the variation of frequency wi atomic number and other properties of X-ray spectr are discussed and shown to be natural consequences Bohr's atomic model. From the experimental dat Prof. Siegbahn demonstrates how it is possible determine the various energy levels in the atom, and hc the levels so determined provide a remarkable confirm tion of the distribution of the electrons in the ato suggested by Bohr from other considerations. The fa that all the lines which these energy levels suggest possible do not occur in the observed spectra is shov to lead to a selection principle similar to that whi holds for the visible spectrum. The author has be most successful in his endeavour to present the theore cal aspect of his subject with a maximum of simplicit The reader can scarcely fail to be impressed by tl remarkable way in which a theory, formulated initial to explain the visible spectrum, is shown to be immec ately applicable to a region of the spectrum where tl frequencies of the radiations are some ten thousar times greater. Prof. Siegbahn makes it clear th much work still remains to be done before all the fac described in the earlier chapters are satisfactori interpreted. Particularly interesting, as a suggestic of further lines of development, is his account Wentzel's attempt to explain the more complicated spectra of the lighter elements as due to the existence atoms from which more than one electron has bee removed.

In the concluding chapters the author deals with tl " white " radiation and with the more indirect metho which have been applied to X-ray spectroscop especially with the determination of energy levels b means of β-ray spectra and ionisation potentials. Tl work in the latter direction has been most successf in helping to bridge the gap between the X-ra region and the extreme ultraviolet. In the form appendices are given some useful tables and a excellent bibliography.

Prof. Siegbahn is to be congratulated on having pr duced a volume which is not only a necessary additic to the library of the X-ray specialist, but is also t be heartily recommended to all who are interested i the advance, experimental and theoretical, in on of the most productive fields of modern physic research.

Lord Avebury's Life and Influence.

The Life-work of Lord Avebury (Sir John Lubbock), 1834–1913. Comprising Essays by Sir Bernard Mallet, Sir Arthur Keith, Dr. A. Smith Woodward, Prof. J. Arthur Thomson, H. St. J. K. Donisthorpe, Dr. A. C. Seward, Sir Michael E. Sadler. Edited by his daughter, the Hon. Mrs. Adrian Grant Duff. Pp. vii+261. (London: Watts and Co., 1924.) 6*s.* net.

THE book under notice contains a short memoir of the late Lord Avebury, and a series of appreciations of his very numerous activities by seven experts. Lord Avebury was an interesting personality, and he covered so many and so varied interests that it requires a symposium to estimate the value of the work he did.

The first of these experts is Sir Bernard Mallet, who dwells upon the political and economic work Sir John Lubbock did whilst he was a member of Parliament. When he was first invited to become a candidate he summed up the objects he wished to achieve as follows: "(1) To promote the study of science both in secondary and primary schools, (2) to quicken the repayment of the National Debt, and (3) to secure some additional holidays and to shorten the hours of labour in shops." It is remarkable how by quiet and steady persistence he in time achieved those reforms which he set out to accomplish. His name will ever be associated with bank holidays. Sir Bernard sums up his power as a politician as follows:

> Sir John Lubbock's whole attitude towards economic questions was characterised by the same sound judgment and common sense. He was, as I have mentioned, in full sympathy with the best economic opinion of his day on fiscal policy, Free Trade, municipal trading, and so on; and in his various addresses and articles on such questions his touch is so sure and confident that a reader might almost imagine that his views had been adopted wholesale from text-books. His scientific habit of mind, no doubt, combined with his practical experience of business, gave him more than ordinary facility in such matters: but he had furthermore the power observable in men of executive capacity of arriving rapidly and without any apparent process of thought at conclusions which, once formed, were apt to remain unquestioned in his mind. This probably accounts for his remarkable clearness in exposition.

Lord Avebury's remarkable achievements in anthropology are dealt with by Sir Arthur Keith. In the middle of the last century, from the late 'forties to the 'sixties, a small company of Englishmen with whom Lubbock was associated—he was quite a boy, for he entered his father's bank in 1849 at the age of 15—entirely revolutionised the idea of the history of man. Constant contact with Charles Darwin, a neighbour of his in Kent, had widened his outlook and that of his fellow-workers; and perhaps the most distinguished of the many distinguished pieces of work that Lord Avebury accomplished was in his "Prehistoric Times" and "The Origin of Civilisation"; both of these passed through repeated editions and are still classics. The words of Sir Arthur Keith are eminently true when he writes: "Let us have done, once and for all, with the prevalent notion that his books on the pre-history of man are the mere accomplishments of a clever compiler. He was an original thinker of a high order."

As a geologist Lord Avebury was chiefly interested in prehistoric man, and his geological publications were not highly specialised in other fields, but his knowledge of geology gave a good background to many of his widely read books. "The Scenery of Switzerland," for example, was much more than a mere compendium or abstract of the works of the Swiss geologists whom he quoted. He wrote from first-hand personal knowledge, and he always had an eminently readable style, so that this book has added greatly to the pleasure of the numerous frequenters of "the playground of Europe."

A very brilliant study of Lord Avebury's work as a zoologist is written by Prof. J. Arthur Thomson. Although his published monograph on the Collembola and Thysanura, an obscure group of insects, is still a standard work of reference, his chief fame rests on his amazing investigations into the behaviour of animals. He was, indeed, as Prof. Thomson says, "the pioneer of the experimental study of animal behaviour." His observations on the colour-sense of bees, the homing of ants and bees, and the behaviour of wasps started a new chapter in the history of experimental zoology. There is a special chapter dealing with his fascinating studies on ants by Mr. Donisthorpe.

Lord Avebury's researches in botany are dealt with by Prof. Seward, who recounts the ceaseless work which he did on the interrelation of insects and plants, the methods of pollination, the form of leaves, buds, and stipules, and last of all on seedlings. His love of beauty and his great gift of exposition are evidenced in all his writings, but nowhere more so than in his writings on the plants he loved so well.

Lord Avebury's business training doubtless enabled him to apportion his time so that no one minute was wasted. How one man could have got through so much, how he could have made so many researches and so faithfully investigated Nature in so many phases is difficult to understand. Doubtless he had many helpers. But this total output, as recorded and appreciated in this book on his life work, is literally amazing, especially when one remembers that he was actively engaged as a successful banker during most of his life.

Our Bookshelf.

The Cultivated Evergreens: a Handbook of the Coniferous and most important Broad-leaved Evergreens planted for Ornament in the United States and Canada. Edited by L. H. Bailey. Pp. xvii+434+48 plates. (London: Macmillan and Co., Ltd., 1923.) 31*s.* 6*d.* net.

THIS handsome volume was compiled for use in the United States and Canada by fourteen American experts in botany, horticulture, and allied subjects; but it will also be of service on the eastern side of the Atlantic, as nearly all the species dealt with can be seen in English parks and gardens. The great diversity of the British climate allows us to grow, in one part or another of these islands, an amazing number of exotic plants, imported from almost every region outside the tropics.

The greater part of the text is concerned with one class of evergreens, the Coniferæ; but the five genera, Larix, Pseudolarix, Taxodium, Glyptostrobus, and Ginkgo, which happen to have deciduous foliage, are not excluded on this account. The other class, comprising the broad-leaved evergreen trees and shrubs, seems to be more sparingly cultivated in the United States than in Great Britain; and only 25 species are selected for description, though some others are briefly mentioned. Acid soils, which are an essential requirement for the proper growth of a considerable number of broad-leaved evergreens, are the subject of a special article by Prof. F. V. Coville, whose experiments should greatly interest cultivators of Rhododendrons.

In the main part of the book, conifers are considered from nearly all points of view, except that of timber production. The use of the different species and varieties for ornament and shelter is the main consideration. A series of articles deal with their effects in the landscape, and their adaptability to different soils and situations. Other articles are concerned with modes of propagation, nursery management, cultivation, attacks of insects, diseases, injuries of all kinds, fungicides, tree surgery, etc. The information given on these subjects by the various experts contains many valuable hints on the choice, cultivation, and care of coniferous trees.

The botanical part of the work is due to Alfred Rehder, the systematist of the Arnold Arboretum. In this establishment there are fine collections, both of living trees and of dried specimens, which have enabled him to draw up accurate descriptions of the conifers in cultivation. He has also provided keys for the genera and species, which render identification easy, even in the absence of flowers and cones. The botanical descriptions are elucidated by nearly 100 engravings in the text. Conifers are very varied in form and colour; and their choice for landscape effect depends largely on a proper knowledge of the habit of each species and variety when fully grown. This is well illustrated by 48 full-page plates, which depict groups and individual specimens growing in New England. These plates are worthy of study by landscape gardeners.

A check-list of all the woody evergreens that are offered for sale in the United States is given at the end of the book, which will serve as a suggestive planting list. There is also an adequate index. We have no hesitation in characterising this handbook as a useful addition to the literature of conifers.

The Modern Theory and Practice of Pumping: a Treatise on the Application of the Reynolds-Stanton Law of Viscous Flow to Modern Pumping Problems and the Flow of Liquids through Pipes. By Norman Swindin. Pp. 364. (London: Ernest Benn, Ltd., 1924.) 42*s.* net.

THE first part of this work is devoted to a general consideration of viscosity, of the motion of viscous fluids, and of the resistance to flow in pipes, with special reference to the relationship between the many empirical formulæ of the exponential type which have been evolved in the past, and the dimensional formula of Reynolds.

The introduction deals briefly with the history of modern hydrodynamics, outlining the relationship between the behaviour of the perfect fluid of the mathematician and of a viscous fluid. Chapter ii. deals with industrial viscometry, with special reference to the liquids with which the chemical engineer may be required to deal. Chapter iii. gives a précis of Reynolds's discussion of the two manners of motion of a fluid, together with later extensions of the theory, and Chapter iv. gives examples of the application of the Reynolds's function in industrial problems. The treatment of this part of the book is excellent, and the various points of application to the problems of the chemical engineer are well brought out.

The second part of the work deals with the many types of pump in use for pumping corrosive, gritty, solid-laden, and viscous liquids such as are not in general handled by the hydraulic engineer. Chapters are devoted to the ram pump, the centrifugal pump, the rotary pump, the air-lift, the displacement pump, and to miscellaneous pumping appliances, particular attention being paid to those types which have been devised to meet special conditions.

While no great space has been devoted to a discussion of the theory of operation, this is adequate for the purpose in view. Special reference must be made to the section dealing with the air-lift pump. This forms one of the most satisfactory discussions yet published of this important but somewhat neglected type of installation. A chapter is devoted to pipe lines and fittings, and another to the pumping of oil for the oil fuel and petroleum industry. In view of the special difficulties involved in pumping such fluids through long pipe lines, this chapter is likely to be of much value.

The book should certainly find a place in the library of every chemical engineer, while engineers in general hydraulic practice will find much that is stimulating and of interest in its pages. It is well printed and excellently illustrated. A. H. G.

Thermochimie. Par Prof. F. Bourion. (Collection de Physique et Chimie.) Pp. xii+363. (Paris: Gaston Doin, 1924.) 25 francs.

THE science of thermochemistry owes most of its experimental data to the work of Thomsen, from 1853 onwards, in Copenhagen, and to the work of Berthelot in Paris from 1865. It was originally inspired by the

idea that the amount of heat liberated in a chemical action was a measure of the energy available from this source, but this is only correct at the absolute zero; at all other temperatures, therefore, endothermic actions can occur, and it is no longer possible to predict from the thermochemical data alone in which direction a chemical action will proceed. On the experimental side also, the science has been limited by a standard of accuracy far lower than can be attained in other physical measurements. This lack of accuracy is the more to be deplored since the heats of formation of organic compounds are based upon the differences between relatively enormous heats of combustion; and the most interesting data (*e.g.* the heats of formation of isomers) contain even larger percentage errors than the heats of combustion through which they are determined.

It is, however, of interest to know that recent developments, in the original laboratory of Berthelot, have led to a very great improvement in the degree of accuracy of the measurements. These are now being obtained within about 1 part in 1000 by using a completely enclosed apparatus, in which evaporation from the surface of the calorimeter and other disturbing factors are eliminated. It is therefore natural that interest in thermochemistry should once again have been aroused in France, and that the latest text-book on the subject should be of French origin. Prof. Bourion has not himself made any important contributions to thermochemistry, but he is familiar with the work that has been done by other investigators, and his book will obviously be consulted by all those who wish to know the present position of the subject.

La télégraphie sans fil : ses applications en temps de paix et pendant la guerre. Par Julien Verdier. Pp. viii + 412. (Paris : Gauthier-Villars et Cie, 1924.) 35 francs.

To every radio engineer who desires to learn the latest practical advances made in radio communication in France we can recommend this book. The historical introduction is not very good and has perhaps a national bias, while the theoretical chapter is too sketchy to be of use to any one but an expert. But the chapters describing practical applications, radio communication during the War, and the French radio stations, contain much novel matter. France has built the two most powerful stations in the world, Melun and Croix-d'Hins. The radio centre at Sainte-Assise is perhaps the most perfectly organised. Methods of using radio waves for discovering masses of metal near the surface of the earth are described. Many of the important radiograms issued during the War are now published for the first time, and the conversations between the Eiffel Tower and Nauen will be instructive to the future historian. The radiograms issued just before the Armistice are highly dramatic.

The French radio system is divided into three distinct services, (1) the Service of the Interior, (2) the Radio Maritime Service, and (3) the Colonial and International Service. The first, which is used for official, special press, meteorological, etc., messages and for time signals, relieves considerably the ordinary telegraph service. Broadcasting comes under this head. The Radio Maritime Service maintains communication with ships at sea and is regulated by the International Rules adopted at London in 1912. Full lists are given of the Colonial and International stations with which there is regular communication. In the last chapter, both the French and the International Rules for radio work are given in full.

Théorie générale sur les courants alternatifs. Par M. E. Piernet. (École d'électricité et de mécanique industrielles.) Fascicule 1. Pp. x + 100. (Paris : Gauthier-Villars et Cie, 1924.) 12 francs.

THIS book explains clearly the principal theorems of the theory of polyphase currents. The mathematical student who has a knowledge of French will have no difficulty in understanding it. The theorems given form an excellent basis which he can use for extending his knowledge. It will be useful, however, to make a few criticisms. When defining the instantaneous power in a circuit (p. 13) the author talks about the quantity of energy *instantaneously* given to the circuit. He defines also the watt current and the wattless current. The reader gets the impression that the current has more to do with the power than the electromotive force. A formal proof is given of the "equivalent" sine wave, and it is concluded that it can in general be used instead of the actual wave. Many practical engineers do make this assumption, but in some cases it will lead to very erroneous results. The so-called "equivalent" sine wave has a different area from the actual wave. The magnetic flux induced in a transformer, for example, when the two waves are applied at the primary terminals, will be different and so also will be the consequent losses in the core. The experimental method of analysing a wave is described, but we do not think that the analytical method given will be of much use. In the last chapter the theory of rotating magnetic fields is discussed in a way that will appeal strongly to the mathematician. Much of this book might with advantage be included as practical examples to illustrate the theory in a mathematical treatise on the calculus.

A Shorter School Geometry. By H. S. Hall and F. H. Stevens. Part 1. Pp. x + 164 + iv. (London : Macmillan and Co., Ltd., 1924.) 2*s*. 6*d*.

THIS volume is much more than a revised edition of the well-known course of "School Geometry" by the same authors : there are differences alike in matter, plan, and presentation so substantial that it may almost be regarded as a new text-book. The authors have followed many of the recommendations put forward in the recent report issued by a Committee appointed by the I.A.A.M. We notice, however, that they have included in the text "proofs" of the fundamental congruence theorems but have excluded "proofs" of the fundamental parallel theorems. This is a curious compromise which it is unlikely will stand the test of time. Both groups of fundamental properties are treated informally in an introduction which runs to 42 pages and also includes some mention of similarity; the latter, however, might with advantage be discussed in greater detail. There is much to be said for developing informally the general principle of similarity with as much emphasis as is now given to the general principle of congruence. The exercises have been increased in number, particularly those of a numerical character : the clearness of the type and the diagrams deserve a special word of praise.

Letters to the Editor.

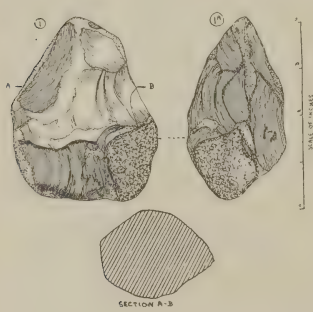
Further Discoveries of Ancient Flint Implements at Cromer.

FOLLOWING upon the discoveries of flint implements referable to the Cromer Forest Bed Series of Norfolk, the Trustees of the Percy Sladen Fund very generously provided funds for the further examination of these and of other associated deposits. The first part of this research is now completed, and has, in my judgment, established the occurrence of flint implements of Early Chellean types at the base of the Cromer Forest Bed, and of Late Acheulean types in some of the glacial gravel above the Contorted Drift. As will be remembered, there was discovered upon the foreshore at Cromer a large series of ochreous specimens, which, while not actually *in situ*, was, from the whole circumstances of the case, referred by me to the lowermost horizon of the Forest Bed.[1]



FIGS. 1 and 1A.—Early Chellean hand-axe from foreshore, Cromer.

It was obviously necessary to endeavour to ascertain by digging if similar ochreous flints occurred in place in some deposit beneath the beach, between the foreshore and the cliffs, at the site where the discovery was made. Such excavations were attempted, but, unfortunately, the water-logged condition of the sand and shingle forming the beach was such as to make impossible any digging in a downward direction, and the work had to be abandoned. Associated with the ochreous specimens upon the foreshore, was found another series of artefacts of a totally different character. These latter flints are usually of a glossy black colour—giving them an appearance of having been black-leaded—and their forms and flaking are clearly divergent from the ochreous pieces.

The occurrence of large quantities of such flints upon the Cromer foreshore, beyond the seaward extension of the beach, is to be explained only on the supposition that, at one time, there existed a bed, or beds, containing these specimens, and that the action of the sea has gradually removed the ferruginous or other material forming the deposits, leaving only the heavier and insoluble residue of flints and other objects intact. This supposition is supported by the following facts. A prolonged examination of the contents of the beds forming the cliffs and the foreshore of the north-east coast of Norfolk has shown that the great bulk of the flints referable to these various deposits differ markedly, and that, for example, it is not possible to mistake specimens in the glacial gravels for those coming from the Forest Bed. Further, a considerable number of the foreshore specimens have, attached to some portion of their surfaces, the remains of a highly ferruginous sandy deposit, which clearly formed part of the bed in which at one time the flints were embedded. Moreover, upon the foreshore, exposed at low water at East Runton—about 2 miles westward of Cromer—there are to be seen large areas of a highly ferruginous bed, the sandy content of which corresponds precisely, in appearance, with that adherent to the specimens found at Cromer. Lastly, an examination of the East Runton deposit demonstrates that it contains implements and flakes comparable, both in colour and in technique, to the ochreous and to the black-leaded series of Cromer. The former assemblage is certainly not so deeply ochreous as that collected upon the Cromer foreshore, but this is a minor difference due, no doubt, to the fact that, at the latter place, the flint-containing bed was richer in salts of iron than that exposed at East Runton. The remains of this bed at this place are surrounded by large numbers of flints, such as occur upon the foreshore at Cromer, and it is abundantly clear that these specimens have been washed out of the deposit to which they lie in such close proximity.

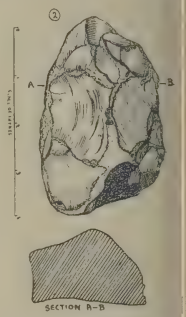


FIG. 2.—Early Chellean hand-axe from foreshore, Cromer.

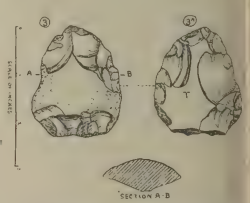
There can be no doubt that this East Runton deposit, which rests upon the chalk, underlies (*a*) an accumulation, representing probably the Estuarine Gravel, containing large mammalian bones referable to the Cromer Forest Bed, and (*b*) the immense glacial deposits and chalk erratics exposed in the cliff at this spot. The implementiferous bed is about 18 inches in greatest thickness, and contains a large number of flints, many of which exhibit the well-known appearance of those found in the Stone Bed beneath the Weybourne Crag, together with pieces of quartz, fragments of bone, and some shells. In fact, at first sight, the deposit bears a very close resemblance to the Sub-Weybourne Crag Stone Bed, material from which it undoubtedly contains, but an examination of the contents leads me to believe that the accumulation must be referred to a later period than that of the Sub-Crag Stone Bed, namely, to the earliest Cromer Forest Bed Stage. Many of the flints found in the East Runton deposit exhibit well-marked striations upon their flaked surfaces.



FIGS. 3 and 3A.—Late Acheulean hand-axe from glacial gravel, Cromer.

In order to give students of prehistoric archæology an opportunity of forming a judgment as to the kind of implements found during my recent researches, I give here illustrations (Figs. 1 and 1A and 2) of two specimens of Early Chellean implements from the foreshore site at Cromer. Both of these are of the "black-leaded" variety. The majority of the Early Chellean "hand-axes" (of which I have now upwards of 40 examples), referable to the base of the Cromer Forest Bed deposits, are of the batiform type—having one face more or less flat, and formed usually by a single flake-removing blow, while the other face is convex and exhibits numerous flake-scars. This peculiarity applies both to the ochreous and to the "black-leaded" specimens. I illustrate in Fig. 2 an implement of the batiform type, while in Figs. 1 and 1A are shown two views of a specimen of a much rarer form, which approximates to the platessiform type, and is more or less rhomboidal in section.

[1] Moir, J. Reid. "The Great Flint Implements of Cromer, Norfolk." (W. E. Harrison, Ancient House Press, Ipswich.)

It is of much interest to note that Early Chellean implements, which correspond in all their main features to those found at Cromer, occur in the lower portion of the well-known palæolithic gravel at Warren Hill in north-west Suffolk. The specimens in this deposit, which show marked signs of transport, exhibit a different coloration and general appearance from the Cromer hand-axes, due to the differing conditions to which they have been subjected. The last-named specimens show a peculiar wearing down of their ridges, and outstanding portions, which is not usually found, so far as my knowledge extends, associated with river-gravel implements. With the hand-axes of the Cromer Forest Bed has been found a large series of scrapers of various kinds, and also many flakes—which, however, cannot be described in this communication, owing to limitations of space.

In the glacial gravel capping the cliff at Cromer, and at East Runton, have now been found two implements of Late Acheulean type. Both of these have been discovered by Mr. Guy Maynard, who on several occasions has accompanied me to Cromer. One of the specimens mentioned, a small and typical hand-axe, exhibiting "basket-work" patination, is illustrated in Figs. 3 and 3A (the surface marked T in Fig. 3A is of thermal origin). When the Cromer research is completed, I hope to publish a full and detailed account of the whole of the results obtained.

J. REID MOIR.

One House, Ipswich.

The Theory of Hearing.

I SHOULD like to express my agreement with the letters which Sir Richard Paget and Mr. Wilkinson have written (NATURE, July 19, p. 87) under the above heading. It seems to me that even if Prof. Scripture is right in stating that the movements of the vocal chords cannot be analysed, he is not justified in concluding that the aerial vibrations thus set up are not analysable either. There is, I believe, massailable evidence that such a conclusion would be wrong; because all workers in this field from Helmholtz and McKendrick to Miller and Bevier are in agreement as to the success of such analysis. Their analyses differ somewhat, it is true, but individual and national peculiarities in vowel production probably account for these. With regard to the piano experiments, I fear that Prof. Scripture (NATURE, August 9, p. 194) has not appreciated the fact that his criticism of Sir R. A. S. Paget and Mr. Wilkinson, namely, that "what a person hears is chiefly what he expects to hear," applies with equal force to himself.

Returning to Prof. Scripture's main argument for one moment, I should like to put a number of questions to him. (1) What experimental proof has he for the statement that the equation for a single laryngeal puff is $y = a.e^{-\epsilon t}$? (2) Are not the variations of pitch of the voice limited in most individuals to about two octaves? (3) Are the variations in pitch in speech more rapid than two octaves per second? If (2) and (3) are answerable in the affirmative, then the results of my experiments quoted in my last letter to NATURE would apply, namely, that a relatively small group of resonators will be affected at any one moment, and that the group thus affected will shift as a whole according to the change in pitch of the voice.

Lastly, may I give some notes on the important point raised by Mr. Wilkinson, namely, as to the damping coefficient of the ear resonators. To commence with, I should like to point out that two additional factors are involved in any attempt to determine the physiological behaviour of the ear, namely, (1) the least amplitude of vibration of resonators of different pitch which will just cause noticeable stimulation of the corresponding hair cells, and (2) the least perceptible difference between the amplitudes of the resonators set up by two immediately successive tones—in other words, the absolute and difference thresholds respectively. It is not difficult to see the importance of these two factors. Two examples will suffice: (1) The ability of an individual to judge if two tones of the same pitch have the same intensity is determined not alone by the difference in amplitude of vibration which these set up in the ear resonators, but also on the ability of the hair cells to perceive the difference. (2) The time taken for silence to follow the cessation of a tone depends not only on the rapidity with which the resonators return to rest, but also on the amplitude of the vibrations to which the hair cells cease to respond.

There are thus three quantities to be determined, the two thresholds mentioned above and the damping coefficient of the resonators. By methods to be described fully elsewhere, I have obtained the following provisional values for these quantities:

The absolute threshold is reached when the amplitude of swing of the resonators falls below 5·8 per cent. of the previous steady value.

The difference threshold is reached when the amplitude of swing of the resonators falls or rises by more than 2·6 per cent. of the previous steady value.

From the damping coefficients the following tuning and persistence coefficients were obtained:

Tone.	Tuning Coefficient.	Persistence Coefficient.
	Per Cent.	
128	9·0	6·5
256	7·5	8·0
512	6·3	9·5
1024	5·4	11·0

The tuning coefficients are the percentage difference of frequency between that pitch which is in tune with a given resonator and that which will produce one-tenth the amplitude of swing which the intune one would have done.

The persistence coefficient is the number of complete swings which would occur in the time taken for the amplitude of the resonator to fall to one-tenth its previous value.

From these values it is possible to make a number of calculations, which can then be compared with the results of experiment. For example, one can calculate the difference of pitch necessary for the differentiation of two successive tones or the time taken for silence to follow the cessation of a tone.

Tone.	Calculated just Perceptible Difference of Pitch in Cents.	Calculated Time to reach Silence in Hundredths of a Second.
128	1·5	6·9
256	1·3	4·3
512	1·1	2·5
1024	0·9	1·5

These calculated pitch difference values compare well with experimental ones given in the table below, except with 120 vibrations per sec., at which the calculated value is too beneficial.

Tone.	Observed just Perceptible Difference of Pitch in Cents.	
	Delezenne.	Külpe.
120	6	...
260	...	1·24
500	1·0	...
1000	0·84	...

The values for "the time to reach silence" would permit a shake or trill of the following number of tones per second to be clearly heard.

Tone.	No. of Notes per Second clearly audible.
128	14·5
256	23·0
512	40·0
1024	67·0

Unfortunately, I know of no extended experimental results by which these values can be checked. They fit, however, Helmholtz's statement that a shake or trill of 10 notes per second, which is clear for tones above about 110 vibrations per sec., ceases to be clear below that pitch.

With regard to the least and greatest differences of pitch between two tones for audible beats, the calculated and observed values appear to fit well. Perhaps I may finish this letter by asking Mr. Wilkinson if these values also fit in with the data at his disposal.

Lastly, being a physiologist, I cannot agree with Prof. Scripture's suggestion (p. 194) that the resonance theory is unthinkable to those who work with delicate human tissues. Neither can I take seriously his proposal that the resonance theory be abandoned and his own substituted. The resonance theory has so far passed every test that I have put to it. Why then think of abandoning it? If I had any doubts lurking in my mind concerning it, or if I thought that it had need to fear rivals, I might, with the editor's permission, tell Prof. Scripture exactly what I think of his theory. But, as neither is the case, I feel there is no need for me to do this. If I have a regret, it is that Prof. Scripture is not as familiar with resonators as he apparently is with delicate human tissues.

King's College, Cambridge.

On Early Sexual Maturity in the Molluscs, *Syndosmya alba* and *Cardium fasciatum*.

IN November 1920, good numbers of the mollusc *Syndosmya alba* round about 15 mm. in length and sexually mature were taken by dredging in the Black Deep near the Edinburgh Lightship. The occurrence of this bivalve, practically on the spot where munitions had recently been dumped, is a matter of much interest, so that observations on the life-history of this form are worth recording. It was suspected at the time that the specimens taken in 1920 were at least six months old, as estimated from material obtained in the sea experimentally, but recently the present writer had the good fortune to obtain a good fall of young ones of this species in a cage which had been in the sea in the River Blackwater in the Thames Estuary area about eight months, *i.e.* from October 22, 1923, to June 7, 1924. In this case the valves of *Pecten maximus* and *Ostrea edulis* were strung on tarred rope in pairs, so that pairs of the shells were in the same relative position as in life. In the cavity of these shells a certain amount of mud accumulated and in this nidus young Syndosmya settled at some time later and grew to a size varying from 6·5 to 12·0 mm. in length. Individuals about 8·0 mm. in length were found to be approaching sexual maturity.

An artificial fertilisation was made on June 8, 1924, from a ripe male and female 11·5 and 12·0 mm. long respectively, after the eggs had matured in the sea-water for one hour. It was found that in less than five minutes the ripe egg threw out a large vesicular transparent membrane; in about three hours embryos in two to seven celled stages occurred, and in twenty-four hours a ciliated larva; in less than forty-eight hours a fully formed trochosphere developed with a fine apical tuft resembling the similar stage in the Gastropod, Patella. In a similar experiment male and female *Cardium fasciatum* 8·3 and 8·5 mm. long were obtained sexually mature, and yielded a thin-shelled veliger in the double egg-case in less than forty-eight hours, and a good shelled larva in four days.

Similar material of Syndosmya and Cardium had been obtained in previous years in a period of three to four summer months, but in circumstances where age determination was less certain.

It is a very difficult matter to grow animals of this kind in the sea and be absolutely certain of their age; in the experiment quoted above there is a faint possibility that some of the Syndosmya may have been washed between the shells, although the chance is very remote, as the cage in which the shells were fixed was specially raised 3 feet from the bed of the sea. An experiment has been devised, however, to obtain more information. A point of interest about the early trochosphere of Syndosmya is that it changes its direction of revolution in the egg-capsule in a rhythmical manner which apparently varies with the physical conditions.

At the same time as Syndosmya and Cardium were growing to sexual maturity, European oysters (*O. edulis*) settled in a similar situation and grew to a size of more than one inch long by one inch deep, while Portuguese oysters (*O. angulata*) grew to as much as 32·6 mm. long by 44·0 mm. deep, although the young oysters of both kinds were mostly less than half an inch long at the end of last year's growth. Thus, although the sexually mature Syndosmya and Cardium cannot be more than eight months old, there is good reason to infer that they may be much younger, especially as the shells showed mostly no indication of a winter ring. It is probable that both these forms mature in summer in about three or four months.

The Reported Transmutation of Mercury into Gold.

IN your account of the reported discovery, by Prof. Miethe, of the transmutation of mercury into gold (NATURE, Aug. 9, p. 197) by the prolonged action of a high-tension electric current upon it, you seem to consider only one way, and that not the more obvious way, of effecting such a transmutation, namely, by striking out a hydrogen ion from the nucleus by some powerful method of disruption. There is another method of effecting such a change, namely, by attaching an electron to the mercury nucleus. Indeed, for some time before Prof. Miethe's announcement it has been clear to me that, by passing a sufficiently high tension discharge through mercury vapour, not merely that such a transmutation might occur, but that it was inevitable, unless our present views of atomic structure are radically at fault.

For consider the collision of high-speed electrons with mercury atoms. A small proportion of these

electrons must be directed upon the nucleus. If they possess sufficient energy to penetrate the external levels of electrons in the mercury atom, they must reach the positively charged nucleus and be captured by it. Since the loss of an electron (as a β-ray) by the nucleus of an element in the radioactive disintegration of an element results in the atomic number of the element in question being increased by one, the gain of an electron by an atomic nucleus must result in the diminution of the atomic number by one. This is quite general. In the case of an isotope of mercury of atomic number 80, the product will be an isotope of gold of atomic number 79. Upon existing knowledge it is simply a question of (1) the potential sufficient to drive the electron through the outer levels of electrons surrounding the mercury nucleus until it comes within the sphere of attraction of the powerfully charged nucleus; (2) whether the exceedingly small fraction of direct collisions with the nucleus that is to be anticipated will be sufficient to enable the gold produced to be detected.

As regards the first, it may be expected that the repulsion of the external shell of mercury electrons will diminish rather than prevent altogether the chance of the radiant electron reaching the nucleus; for once the shell is penetrated, the resultant force on the radiant electron must be on the average an attraction. Hence I had arrived at the conclusion that, not the transmutation, but the chemical detection of the gold produced, would probably be the more formidable experimental difficulty.

Of course, I need express no opinion on the correctness of the experimental results recorded, which naturally will have to be very rigorously confirmed by further work. I merely wish to point out that no atomic disruption is necessarily involved, and that, so far from conflicting with existing knowledge, the result in a sense follows naturally from it, the only question being one of the sensitiveness of the experimental methods of detecting gold.

Oxford, August 9.

The Transmission of a New Plant Virus Disease by Insects.

In a paper read to the Imperial Botanical Conference held in London this year, I have described a variegated condition of a number of Graminaceous plants, characterised by chlorosis of the leaves in narrow broken stripes parallel to the veins and a reduction in the power of growth of the plant. In maize it has been recognised for many years as a factor limiting production in the coastal and midland areas of Natal, and was described as long ago as 1901 by Fuller (First Report, Government Entomologist, Natal). Similar conditions are found in sugar cane and a number of other grasses.

I have given evidence in the paper mentioned for the belief that this variegated condition is a disease of a type similar to the now well-known mosaic disease of sugar cane, maize and other grasses, but is not identical with it. These conclusions were at that time based upon general observations and lacked evidence of experimental transfer. Recent work upon insect-transmission of the disease occurring in maize affords confirmation of the conclusions originally reached.

In a series of experiments I have been able to demonstrate the ability of the adults of a Jassid leaf-hopper, an undescribed species of the genus Balclutha, to produce the disease in healthy maize plants when transferred to them from diseased plants. Hoppers taken from healthy plants have failed to produce the disease. All plants have been protected from outside infection for the whole period of the experiment, and no control plants have developed the disease. The role of *Aphis Maidis* Fitch as the vector of mosaic disease between sugar cane, maize, and certain grasses has been established by several workers, and has been confirmed by me under South African conditions. All attempts to secure infections of this new disease through the agency of *A. Maidis* have failed.

The experiments referred to have been carried out with leaf-hoppers collected in diseased maize fields. A proportion only of such individuals are capable of producing the disease, although the maize may be almost universally infected. No individuals, however, which have been once proved to be vectors, have failed to transmit the disease to all plants to which they have been subsequently moved.

Preliminary attempts to secure transmission of the disease from maize to sugar cane and grasses have not succeeded. It must, therefore, remain in doubt whether it is a single disease which occurs in the different hosts, although field observations and similarity of symptoms would point to this conclusion.

Isotopes of Mercury and Bismuth and the Satellites of their Spectral Lines.

In his letter to Nature (May 31, p. 781), Prof. Runge criticised the result of measurements on the satellites of mercury and bismuth lines in connexion with the isotopes, which I and my co-workers have communicated to Nature (March 29, p. 459), as not convincing. It gives me much pleasure that our note has attracted the attention of such an eminent spectroscopist and mathematician as Prof. Runge. The aim of that note was to show that the wave-length differences $\delta\lambda$, according to our formula, which involves the masses of different isotopes, are found among the satellites of mercury and bismuth lines. Prof. Runge discarded *i* and *j*, and took wave-length differences of observed satellites at random, which is contrary to our view, as regards the selection. The example given by Prof. Runge seems to me to be *lauter Zahlenspielerei*.

Perhaps the lines we have cited have too many satellites to incur a criticism; there are, however, many lines with a small number of satellites, and in which the number of selections is but limited. I can cite many such examples, but as the result obtained on satellites of twenty principal lines of mercury has already appeared in the *Japanese Journal of Physics*, vol. ii., pp. 121-162, the publication of which was much retarded by the disastrous earthquake, I consider it needless to occupy the columns of Nature with the details. We have obtained more than 130 coincidences with our formula, within the limits of errors of observation, in mercury lines from the yellow to the ultra-violet region, so that the probability of its validity is very great, and cannot be considered as due to mere chance. The report on bismuth lines will shortly appear in the above Journal.

If we completely separate the isotopes, investigate the difference between the satellites and confirm our result, the proof will no more be open to criticism. Only partial separation of isotopes is at present possible, but even this will help us to study the intensity difference of the satellites, by which the present question can be in some degree settled more directly than by the arrangement of the satellites.

The Cooling Power of the Air in Trains, Trams, and Buses.

By LEONARD HILL, F.R.S., with the co-operation of M. BRAD (from the National Institute for Medical Research).

THE body resembles a motor-car engine in that it is producing heat by the combustion, not of petrol but of food, and, just as the car has a radiator, so has the body—namely, the skin—in order to lose heat and keep at body temperature, that is, the temperature at which the living tissues have to live. During muscular exercise, about four times as much heat is produced as work, and when hard exercise is taken, such as climbing, the heat production of the body may be five times as great as when sitting at rest. The loss of heat is controlled, just as the production, by bodily mechanisms. To accelerate heat loss, the skin flushes with blood and perspires; clothes are thrown off and the body fanned. Over-warm stagnant atmospheres and over-clothing check the production of body heat and lead to disinclination to exertion, loss of appetite, and, in time, to debility. Cool surroundings and light clothing, on the other hand, increase the production of body heat, tone up the body, stimulate appetite, impel to activity, and generally improve health.

The ordinary thermometer indicates the average effect of the temperature of the surroundings on itself. Unlike the body it does not produce heat. If a fan is set to blow about the air of the room in which it hangs, its reading does not alter. The body, on the other hand, is very effectually cooled by the fan. The thermometer is, then, an untrustworthy guide to ventilation. The kata-thermometer has been introduced to remedy its defects. This instrument has a bulb which is warmed to just above the average temperature of the human skin, and its rate of cooling is measured during a drop of five degrees, namely, between 100° and 95° F.

In this way the power of the air in any locality to cool a surface approximately at skin temperature can be measured. The measurements are made in millicalories per sq. cm. per second. The bulb of the instrument is roughly the size of the end joint of the thumb. The big masses of the body are cooled less rapidly, having a smaller surface in proportion to their bulk. The kata-thermometer does not, then, actually measure the cooling effect of the air on the human body, but is a valuable indicator of comfortable and healthy conditions.

In rooms kept fresh and warm enough for sedentary work, the cooling power is found to be about 6. In stuffy rooms 4, or even less; in rooms rather cold for comfort, 8. Out-of-doors, where the wind blows, cooling powers are higher; for example, 10 on a genial summer day, 20 on mild winter days, 40 on cold winter days. The open-air worker is stimulated by much higher cooling powers than the sedentary workers, even when the temperature is the same indoors and out, owing to the movement of the air out-of-doors.

As we have said, an adequate cooling power of the air is required to keep "the fire of life" from burning too feebly, to tone up the muscles, invigorate the nervous system, and make keen the appetite and efficient the digestion and action of the bowels.

It has been shown that exposure of the naked body of children to sun and open air, with of course wise prevention of over-cooling, has a wonderful curative effect on states of debility, rickets, and surgical tuberculosis. An adequate increase of cooling power puts up the basal metabolism, that is the heat production of the resting body, even 50–100 per cent. We know that thousands of clerks, shop assistants, factory hands taken from lives spent in monotonous over-warm places were changed from feebly developed, nervous, dyspeptic men into strong healthy soldiers by training in open-air exercises during the Great War.

Severely exposed to weather in the trenches, these men suffered far less from catarrhal diseases than those who continued in employment in cities. The soldiers caught "colds" not in the trenches, but when on leave and infected by close contact with "carriers" in the crowded places of cities. Americans overheat their houses and suffer from catarrhal complaints. The death-rate from pneumonia in U.S.A. has not gone down with that progress in medicine which has notably lowered the death-rates from most other diseases. While exposure to the open air, with the invigorating effect of cool winds and daily exercise, is necessary for all who want to attain full health and enjoyment of life, people, mistakenly attributing the origin of catarrhal disease to exposure to cold, have in the past demanded the over-heating of railway carriages and shutting of windows and the closing in of the roof-seats of trams. Suggestions recently have been put forward for the heating of trams, and the roofing over of the outside seats of buses has been discussed. There have been many who have wished, and some more courageous who have struggled to secure the opening of windows in trains, and these last have been ridiculed in the Press as "open-air fiends" by journalists who are habituated to the stuffy over-warm newspaper offices of Fleet Street. Soldiers, however, hardened in the trenches, on returning from the Great War demanded greater opening of windows in trains, and this habit of open windows has of late become more general.

People are beginning to realise that catarrhal infections are spread by wrong conditions of the atmosphere indoors, and by repeated massive doses of microbes inhaled from "carriers" who sneeze and cough in close crowded places. Even comic artists and artists of patent medicine advertisements now try to illustrate the happenings of such infection. As tube trains and trams are closed up more than buses, and as people continue to dispute over the opening of windows in steam trains, it seemed worth while measuring the cooling powers of the air by means of the kata-thermometer in such trains with windows shut or open, and in tube trains, trams, and buses, comparing in these last the inside and outside. The temperature of the air was also taken and the velocity of the air movement calculated from a formula which allows the kata-thermometer to be used as a very sensitive anemometer. The following are the average results of observations made when conditions were best in the non-crowded

parts of the day, in mild or cool weather, during September and October of 1923.

The standard dry kata-thermometer cooling power suitable for sedentary work in ordinary clothing is 6. Lower cooling powers produce stuffy sensations and require less clothing. If people used foot-warmers, and in some cases wore more clothing when at sedentary work, they could easily bear windows open and a cooling power of 8, or even 10, and have the great advantage of breathing cooler, cleaner air. A sanatorium ward is best kept at such a cooling power as 10. In travelling to and fro wearing outdoor wraps, people can, with advantage, be stimulated by wind giving much higher cooling powers than 6. The bus stands pre-eminent in this respect, and healthy people who enjoy a blow in the fresh air and recognise the good effect of this on health rejoice in the open roof-seats of the bus. The cooling powers outside the bus were 10-31 against 4-8 in the tram. It is regrettable that the roof-seats of trams were ever closed. Those of buses certainly should not be. A removable rain screen open at the sides is all that is wanted in bad weather.

Tubes and steam trains with closed windows and trams are relatively stuffy places, cooling powers 4-10, compared to outside of buses, cooling powers 10-31, and steam trains with windows open, cooling powers 9-19. The seat facing the engine in the steam train with window open is recognised to be much cooler than that with the back to the engine; by how much on cool autumnal days the figures show, 7-12 against 9-19. The cooling power at a seat facing the engine can be doubled or even trebled by opening the window.

The figures also show that movement of air and not temperature is the chief factor at work.

In steam trains with windows open and on the outside of buses, massive infection with the microbes from "carriers" is impossible.

The British Association at Toronto.

(From our Correspondent.)

Toronto, August 10.

OPPRESSIVELY hot weather during the first half of this year's meeting of the British Association at the University of Toronto has made the excursions into the neighbouring countryside particularly popular among the 2600 men of science and citizens who have enrolled as members to the present date. Thunder showers at night have, however, cooled down the hot lecture rooms and rendezvous periodically, and have thus made meetings possible without interfering with communication in the daytime between the score of University buildings utilised for them. The overseas party, numbering 573, was fêted on the way through eastern cities, and most members of it have been given hospitality in private houses in Toronto. Others, with more than three hundred men of science from the United States, are quartered in University residences. Hart House, which is the social and recreational centre of the male University life, has been thrown open to men and women, and the dining-room has been extended to seat six hundred. The Toronto Board of Trade has been responsible for the enrolment of more than one thousand citizens, and the balance of local members is drawn from adjacent towns, many coming in every day for the meeting, so that the hotels are full.

The Convocation Hall of the University of Toronto, seating eighteen hundred people, was packed on Wednesday night, August 6, when Sir Ernest Rutherford vacated the president's chair for his successor, Sir David Bruce. While lightning flashed across black skies outside the building, Sir Robert Falconer, president of the University, welcomed the visitors and said that Canada needed the stimulus which this visit of the British Association would afford. Prof. J. C. Fields, president of the Royal Canadian Institute, also expressed the welcome of the hosts in the name of the Institute. Prof. J. C. McLennan, chairman of the general and executive committees, moved the vote of thanks to Sir David Bruce for his address.

Representative overseas delegates were received by Cabinet ministers in the Parliament Buildings on Wednesday afternoon, August 6, when the Hon. George H. Henry, senior Government minister, extended the hospitality of the Province to the Association. Sir Ernest Rutherford replied on behalf of the delegates. On the evening of August 7, a reception was given by the trustees and directors of the Royal Ontario Museum of Archeology, and was attended by two thousand people, including nearly all the members of the overseas party. The guests were received by Mr. J. B. O'Brian, the Hon. Charles McCrea, the Hon. Dr. Cody, and Mrs. Cody. Many social events have been held, including luncheons, teas, dinners, etc., arranged by

local societies and numerous private individuals. Saturday, August 9, was devoted to excursions, of which those to the Niagara Falls district were most popular.

The popular and citizens' lectures have been thronged. On Thursday, Sir Henry Fowler lectured on metallurgy and its influence on social life; on Friday, Mr. Julian Huxley on control of growth; and on Saturday, Prof. Eddington on relativity. The first children's lecture by Sir William Bragg, on Friday, was most enthusiastically received. Popular meetings and lectures are being broadcast and picked up all over America. The scientific sessions are attracting wide attention, Toronto newspapers devoting several pages to them daily, while the Canadian press generally is giving prominence to them, also the leading United States journals. The meeting is in every way a successful one, and the attendance is satisfactory. Prof. J. L. Myres, general secretary of the Association, praised the local arrangements when speaking at a dinner tendered to visiting Freemasons by the University Lodge on Saturday.

A party of geologists is making a tour in northern Ontario on August 14-19; one of botanists is visiting Temagami Lake district on August 14-18; and one of agriculturists is to visit the Ontario Agricultural College, Guelph, on August 15. Three hundred members are taking part in the general excursions to the Pacific coast, leaving on Sunday, August 17, arriving at Vancouver on August 25, and returning to Toronto on September 3. There will be meetings at Saskatoon, Edmonton, and Vancouver, and halts at all points of scientific or scenic interest. The party goes out by the Canadian National Railway and returns by the Canadian Pacific. Many visitors from Great Britain are making lecture tours in the United States before returning home.

Prof. Horace Lamb has been elected by the General Committee president of the Association for the meeting next year in Southampton.

At a special convocation of the University of Toronto on Wednesday night, August 13, the degree of Doctor of Science, *honoris causa*, is to be conferred on Sir David Bruce, Sir Ernest Rutherford, Sir John Russell, and Sir Charles Parsons.

The three remaining addresses of presidents of Sections were delivered on Monday, August 11, and are described below.

Analysis of Crystal Structure by X-rays.

In his address to Section A (Mathematics and Physics), the president, Sir William H. Bragg, gives a very useful summary of the present position and the limitations of the new methods of analysing crystal structure by means of X-rays. He first discriminates three distinct stages, namely, (1) the measurement of the angle at which X-rays of a given wave-length are reflected by a set of identically similar planes within the crystal; (2) the use of the angular measurement to find the spacing of the set of planes, and hence the linear dimensions of the crystal-unit cell; and (3) the combination of the spacings of three different sets of planes to afford the volume of the unit cell. From these fundamental determinations, and a knowledge of the specific gravity of the crystal, the number of atoms of various kinds contained in the cell are found; and, as the proportion of the various kinds is the same as in the molecule, the number of molecules, one, two, three, four, or rarely more, comprised in the cell is afforded. By the repetition of this cell, in accordance with the degree of symmetry developed, without any new features, the crystal is built up.

The final aim of the X-ray analysis is to determine the arrangement of the molecules, and of the atoms comprising the latter, in the crystal-unit cell. Sir William Bragg emphasises, however, that the only measurement which the X-rays make directly is that of the distance separating any atom in the crystal from any other nearest adjacent one which is of like kind and condition of environment, from which the outlook would be exactly the same and with similar orientation. Any other measurement of distance is an indirect one made with the aid of some additional crystallographic (physical or chemical) reasoning. It is not possible to measure directly by X-rays the distance between two atom-centres within the same cell. For example, in the two-molecule crystal-unit of naphthalene we cannot measure the distance separating one carbon atom from another in the same dimolecular cell, even those of the two separate molecules (which are differently orientated); the measurements afforded are those between any atom and its nearest neighbours exactly like itself in the three principal (axial) directions; that is, belonging to different adjacent cells, these distances being the lengths of the edges of the unit cell. Fresh considerations, such as the knowledge that naphthalene has a centre of symmetry, are required even to define the distance between the centres of the two molecules in the cell; or as in the case of rock-salt, the knowledge of the full crystal symmetry is needed to give us the distance between adjacent sodium and chlorine atoms, the X-ray measurements only affording that between any two sodium atoms, or any two chlorine atoms. Hence, the work of the crystallographer is absolutely necessary, especially as to symmetry and the polarity due to lack of it, exterior angles and the crystal elements derived therefrom, and the physical properties, if the measurements by X-rays are to have their full value. It is a great gain that this has now been so clearly stated.

Sir William Bragg then shows how the X-ray work combined with all these other available sources of information, is enabling us to fix on the particular one of the 230 modes of interior arrangement of atoms possible to crystals, which occurs in the crystal under investigation, and incidentally shows that all cases investigated have conformed to one or other of these modes. The lesser problem of allocating the crystal to its proper class among the 32 differently symmetrical classes of crystals has consequently been solved in most cases with comparative ease. But again, it must be emphasised that the X-ray measurements alone do not permit of so satisfactory a result being attained.

Sir William Bragg also makes it clear that the alarm exhibited, when the first X-ray results were published, as to the apparent disappearance of the molecule, was a "mare's nest." There is nothing whatever to suggest a complete disruption of the alliances within the molecule so successfully studied and brought to light by

the chemist, and it is now certain that the conclusions of chemistry are valid for and carried into the solid crystal as well as into the liquid, for the chemical molecule takes its place as such in the crystal structure with very little change.

It is thus in the combination of the results of the X-ray analyst with those of the crystallographer, the physicist, and the chemist that future progress in the elucidation of the structure of the fully developed solid —the crystal—must be looked for. In thus unambiguously setting forth the limitations of the new method by use of X-rays, and the absolute need of collaboration in the study of crystals and solids in general, the president of the Section has rendered a special service.

LIFE-CONTROL.

PROF. F. W. GAMBLE'S presidential address in the Section of Zoology is an example of strong, matured thinking. It is futuristic rather than a retrospect of the things done and thought in the biology of the immediate past. Seizing on the present methods of experimental embryology it sees in them something pregnant with results that must profoundly modify future biological speculation. Can those results be seen, even if only in a vision, and what may be their nature? The address is an innovation that must be welcome to members of the Section.

More and more biology pries into the nature of the process that makes a specific organism from an apparently undifferentiated egg. This process, whatever it is, must be potential in the egg, becoming kinetic from the moment when the spermatozoon—the "Orpheus that visits the cold Eurydice," the "winged key that unlocks the imprisoned one"—passes through the bounding membrane and sets up the releasing transformation that results in embryonic development. The process is not in the outer environment which, while nurturing in precisely the same way the eggs of a hen and a duck, yet makes of the one a chick and of the other a duckling. Past conceptions of the nature of the developmental process were curiously naïf; they conceived of the ovum about to divide as an assemblage of parts, jumbled together in some way, a chaos of parts but nevertheless parts that were preformed and extended. Something called the "organisation" was supposed to usher the parts into place, laying down, in ordered fashion, the organ-systems, organs and tissues of the embryonic body. Then came the study of aberrations of development to perplex and obscure this simple conception. The organisation existed in the undivided ovum, leading to the segmentation of the latter, so that a number of blastomeres came into existence, each normally giving rise to a different part of the embryonic (and so also the adult) body. Yet the experimentalist could literally shatter the organisation to bits and find that each bit became another organisation (for each blastomere could regenerate a whole embryo). He could divide it in an infinity of parts without impairing it. Thus the egg and its parts, or the embryo and its parts, were autonomous and capable of regulation. The study of the nature of the organisation became the study of life itself—and it became (to many minds) a problem incapable of solution on the classic physico-chemical hypothesis of the nineteenth century. To an increasing number of biologists life becomes an ultimate natural category sharing, with matter and energy, our conception of the universe.

Now among the pregnant methods of present-day embryology there is this: it has become possible to study the mode of operation of the organisation in the developing egg and in the adult, multicellular organism (and it is essentially the same in each of these cases). In the egg the organisation radiates from a focus: in the adult it radiates from an apex or head. The components of the radiation are from head to posterior body regions along the longitudinal nervous axis; from nervous axis to right and left in bilaterally symmetrical animals, and from nervous axis to the ventral regions (in vertebrates), or to posterior regions (in an insect). Along each of these radiative paths the intensity of the control exercised by the focal region diminishes with the distance; there are metabolic gradients and these are demonstrable by various chemical methods. The gradient expresses the degree of positive control which the head region holds upon the functioning of the bodily organs and tissues. This apical control is one of quickening, urging, and directing of physiological activities. The possibility of control is, so to speak, vested in the head, or apical region, which reaches out into the outer world by its distance receptors, ever seeking to increase its environment. Environment and organism, reciprocal activities, are one—that which we call ordered life.

Yet, because the intensity of quickening and directing diminishes with the distance from the focus, there can be physiological isolation of a bodily part—limited, of course, and it may be transient. In the absence of control the part rests—it may be periodically. While it rests its potential rises and when it again comes under the focal control its functioning quickens. So in reserve organic material, two kidneys or testes, one of which may be enough for normal bodily activity, there is periodic alternation of rest and activity. But in the rest consequent on the removal of control there is still the urge of life, for the potential of the part increases. Should the focal control not be re-established what happens? There is always the tendency to individualisation, and the organism may segment and multiply—thus in a dividing Planarian worm the metabolic gradient shows a peak at the region where segmentation will occur. So also we seem to be able to interpret the formation of malignant tissue. Removed from the control of the cerebrum, which blends the activity of the part with those of all other parts of the body the intensity of life may still increase during this resting phase. Then connective tissue, or mammary gland, or testis attains higher metabolic potential, and still drawing on the circulating nutritive materials it endeavours to function; it cannot do so in normal fashion because it is undirected, and it proceeds to proliferate, passing into the cancerous condition.

And here we see, stated as an inference from experimental results, something of the terribleness of life—that which is sinister because it is disorderly. There is a "submerged recessive life" charged with activity, ever seeking to expand or grow. Specific organisations deploy this in ordered morphological and functional varieties. Given this "grace of organic regulation" and the life that incessantly insinuates itself into inert

matter assumes the hierarchical forms that evolution shows us. Without it and we see in life something inchoate but, in a way, fœtid and malignant: something suggested to us by the cancerous tumour or the luxuriantly living and rotting tropical jungle. Here, and in the backwaters of organic evolution—the "living fossils" that are poised between extinction and stability, or the primitive and unprogressive human societies—we see the life of the future: the inextinguishable vital impulse that waits on the ordering control that will lead to its deployment in new organic forms.

Problems of Crop Production.

In his address as president of Section M (Agriculture), Sir John Russell reviews the present position of agricultural research as compared with that occupied when the British Association visited Toronto in 1884. Up to that time the man of science had been occupied with the problem of how to feed the plant. Agricultural science was regarded as simply a branch of chemistry; but, during the last forty years, many new problems involving the biological sciences had presented themselves for solution. These problems are related to the growth of the plant as affected by inherent and environmental variations. Sir John Russell points out that, whereas the great discovery during the early period was that the plant could be fed by "artificial" substances, the most pregnant discovery of the second period was that the plant is plastic; by methods which are under scientific control it can be modified in desired directions, and thus be induced to give results that mere feeding cannot accomplish. Following the pioneer labours of Bateson, astonishing practica results have been reached by such workers a Biffen in England, Nielsen Ehle in Sweden, an the Howards in India. But the science of genetic is only on the threshold of what it may ye accomplish.

Sir John Russell then goes on to review, in detail recent advances that have been made in the science with which he is particularly concerned at Rothamsted He emphasises the pressing need for subjecting the grea mass of material that has now accumulated to statistica analysis. In regard to the numerous empirical dat from "field" experiments, Sir John Russell is o opinion that no advance can be expected until som fresh opening is discovered by scientific workers. Wit regard to the more rigid data accumulated by labora tory workers, the view is expressed that the greates field for discovery lies in the direction of linking u plant nutrition studies with those of the soil solution the latter being explored in the light of the physico chemical interactions between soil and soil water. O the more general issues Sir John Russell is insistent o the need for fuller co-operation between all classes o scientific workers—for team work which shall includ workers of all nations. But when all is said and done the great expenditure of time and money now bein incurred in agricultural research can only be justifie by abandoning the view that the economic end alon is worthy of the effort. The address closes with a eloquent appeal for a wider vision, for an effort t upraise country life by revealing to the countryma "something of the wonder and mystery of the ope spaces in which he dwells."

Obituary.

Prof. J. Wertheimer.

THE death, on August 9, of Prof. Julius Wertheimer, at sixty-four years of age, deprives both science and technical education of a most active and stimulating worker. Since 1890, when he was appointed principal of the Merchant Venturers' Technical College, Bristol, he took a leading part in promoting scientific and technological instruction in the city, with the result that, when the University of Bristol was established in 1909, the faculty of engineering was instituted at the College, with Prof. Wertheimer as dean of the faculty and also professor of applied chemistry.

Prof. Wertheimer was educated at University College, Liverpool, and Owens College, Manchester, and was headmaster of the Leeds School of Science and Technology from 1887 to 1890. He was a fellow of the Institute of Chemistry, the Chemical Societies of London and Berlin, and the Physical Society of London. He was for ten years hon. secretary of the Association of Technical Institutions, and was the author of textbooks of practical chemistry and of scientific and educational articles in various journals, including Nature. His long experience and wide knowledge of all matters relating to technological education at home and abroad made him a very valuable member of many committees. He served on the Council and Senate of the University of Bristol, the Teachers Registration Council, the Education Committees of the Gloucestershire County Council, the Bristol City Council, the British Science Guild, and other bodies In recognition of his services to science and educatio the degree of doctor of science, *honoris causa*, was con ferred upon Prof. Wertheimer by the University o Bristol in 1911. He also received the honour o Officier d'Académie de France in 1906.

Miss Katherine A. Burke.

By the death of Miss Katherine A. Burke, University College, London, has lost an excellent teacher who was untiring in her devotion to the academic, social, and athletic life of the college. Graduating at Birkbeck College, Miss Burke began her career at University College, in 1898, as a research assistant of the late Sir William Ramsay, and she took a share in the research emanating from the chemical laboratory at about this time. Later, she was appointed to the chemical staff, and was the first woman teacher directly concerned with the teaching of the undergraduates of the college. Miss Burke's original work included research on thorianite, the oxides of chlorine, the Joule-Thomson effect, the chemical dynamics of the alkyl iodides, and the absorption spectra of alcoholic solutions of nitrates. The paper on chemical dynamics, with Prof. F. G. Donnan (Journ. Chem. Soc., 1904, 555), showed that the order of reactivity of the alkyl iodides varied with the type of chemical reaction investigated, and hence it was not possible to ascribe their reactivity

) a uniform cause, such, for example, as a dissociation f the iodides into ions. A research, published jointly ith Prof. E. C. C. Baly and Miss Effie G. Marsden ournal. Chem. Soc., 1909, 1096), on the absorption pectra of the aqueous alcoholic solutions of nitric acid nd lithium, ammonium, and silver nitrates in relation the ionic theory, afforded strong support for the heory of hydrated ions. It was found that the miting conductivity and the persistence of the absorp- on band of these solutions showed a minimum at hree per cent. of water. During the War, in addition her work in connexion with the Voluntary Aid Detachment, Miss Burke found time to assist in the preparation of synthetic drugs, which were so badly needed at that time.

Towards the end of her life, Miss Burke's activities were absorbed in the social and athletic life of the college, particularly in connexion with the acquisition and organisation of the sports ground for women students at Perivale.

We regret to announce the death of Mr. Charles Leudesdorf, fellow and vice-regent of Pembroke College, Oxford, registrar of the University of Oxford, and author of a number of papers on mathematical subjects, on August 10, at seventy-one years of age.
